Revised Salem Canal Screening-Level Ecological Risk Assessment
Chemours Chambers Works
Deepwater, New Jersey

Dear Ms. Kavvadias:

Attached please find a copy of the Revised Screening-Level Ecological Risk Assessment (Revised SLERA) completed for the Salem Canal at the Chemours Chambers Works complex in Deepwater, New Jersey. This document represents a revision of the SLERA submitted to the U.S. Environmental Protection Agency (EPA) and New Jersey Department of Environmental Protection (NJDEP) in April 2017. The Revised SLERA incorporates surface water, bulk sediment, and pore water data collected in December 2018 to further characterize areas of elevated ecological exposure identified in the April 2017 SLERA. In addition, EPA and NJDEP comments on the ecological risk assessment approach presented in the April 2017 SLERA have also been addressed in the Revised SLERA.

If you have any questions or would like to discuss the Revised SLERA further, please email me at Andrew.S.Hartten@chemours.com or call me at 302 773-1289.

Sincerely,

A handwritten signature in black ink, appearing to read "Andrew S. Hartten", written in a cursive style.

Executive Summary

This *Revised Salem Canal Screening Level Ecological Risk Assessment* (Revised SLERA) was prepared on behalf of The Chemours Company (Chemours) for the Salem Canal at Chemours Chambers Works (the site) located in Deepwater, New Jersey. The SLERA was conducted in accordance with U.S. Environmental Protection Agency (EPA) *Ecological Risk Assessment Guidance for Superfund*, as requested by EPA in a November 18, 2014 letter (ERAGS; EPA, 1997). This document represents a revision of the SLERA submitted to the EPA and New Jersey Department of Environmental Protection (NJDEP) in April 2017. The Revised SLERA incorporates surface water, bulk sediment, and pore water data collected in December 2018 to further characterize areas of elevated ecological exposure identified in the April 2017 SLERA and incorporates NJDEP and EPA comments on the April 2017 SLERA.

The purpose of this Revised SLERA is to evaluate potential risks to ecological receptors exposed to site-related constituents under current conditions in the Salem Canal adjacent to Chambers Works. Based on the phases of investigations conducted in the Salem Canal, two potential exposure areas are evaluated in the Revised SLERA:

- **Former Seep Area:** Evaluation of exposure to seep-related constituents in environmental media within the Salem Canal that are associated with the historical discharge of impacted groundwater from the Dye and White Products AOCs located adjacent to the canal. The installation of a sheet pile barrier (SPB) has effectively eliminated the groundwater pathway; however, the historical discharge of impacted groundwater resulted in the migration of seep-related constituents to subsurface and surface sediments within the Former Seep Area.
- **Canal-Wide Area:** Evaluation of exposure to potential site-related constituents, including metals, volatile organic constituents (VOCs), polycyclic aromatic hydrocarbons (PAHs) and other semi-volatile organic constituents (SVOCs), polychlorinated biphenyls (PCBs), and pesticides in environmental media that may be associated with site-related pathways outside of the Former Seep Area, including historical or current outfalls. The Canal-Wide Area was further divided into three assessment reaches. Reach 1 and Reach 2 were located between the site property boundary and Munson Dam; the Tidal Reach extended from Munson Dam to the Delaware River.

The scope of the Revised SLERA includes Steps 1 and 2 of the ERAGS guidance (EPA, 1997). Steps 1 and 2 were used to identify constituents of potential ecological concern (COPECs) in bulk sediment, sediment pore water, and surface water to support a scientific management decision point (SMDP) regarding the need for further risk characterization. ERAGS Section 3.2 was included to reduce uncertainty in the Revised SLERA conclusions and to refine the recommendations presented in the report. In addition to EPA ERAGS, exposure evaluations were consistent with NJDEP *Ecological Evaluation Technical Guidance*, where applicable (NJDEP, 2018).

Conclusions and recommendations for the two exposure areas of the Salem Canal that were evaluated in the Revised SLERA are presented below:

- **Canal-Wide Area:** The characterization of ecological risk in the Canal-Wide Area indicated limited, localized potential for adverse effects to the benthic invertebrate community and negligible potential for adverse effects to fish and semi-aquatic wildlife potentially foraging throughout the Salem Canal. The results of the refined exposure evaluation indicated that the potential for adverse effects

within the Canal-Wide reaches was limited to benthic invertebrates in localized areas adjacent to historical outfalls. Sediment characterization sampling in 2018 further defined the limited spatial extent of elevated concentrations adjacent to these outfalls. Given that exposure was localized at select sampling stations adjacent to former outfalls, community-level effects to the broader benthic community within the Canal-Wide Area are not likely. Consistent with previous investigations, surface water quality in the Salem Canal is not adversely impacted by site-related constituents; therefore, the potential for adverse effects to the fish community through direct contact exposure to surface water is negligible. An additional evaluation of potential dietary exposure to fish indicated minimal potential for adverse effects. Potential exposures to semi-aquatic wildlife via ingestion pathways in the Salem Canal are not unacceptable based on modeled dietary doses that were below toxicity reference values (TRVs) and the limited opportunity for exposure due to a lack of available habitat. Based on the overall findings for the Canal-Wide Area, no unacceptable risks were identified for ecological receptors. Therefore, no further investigation or monitoring of the Canal-Wide Area is warranted based on ecological risk.

- **Former Seep Area:** The characterization of ecological risk in the Former Seep Area indicated limited potential for adverse effects to the benthic invertebrate community. Given the limited size of the Former Seep Area, the survival, growth, and reproduction of the benthic community was the only assessment endpoint identified for this exposure area. Evaluation of current exposure to the benthic invertebrate community within the Former Seep Area based on bulk sediment and pore water data collected from 2015 to 2018 indicate that the potential for adverse ecological effects is limited and that significant reductions in seep-related constituent concentrations in bulk sediment have reduced overall exposure. However, continued monitoring of exposure conditions within the biologically active zone (BAZ) will be conducted in 2020 to further support the weight-of-evidence evaluation of natural recovery in sediment within the Former Seep Area following the installation of the SPB.

Given the limited ecological exposure in the Former Seep Area under current conditions and the potential for the degradation of seep-related constituents over time, a framework to evaluate the monitored natural recovery (MNR) of sediment (MNR Framework) was submitted to EPA and NJDEP (URS, 2015). Specific recommendations for future monitoring within the Former Seep Area based on the MNR Framework were presented in the *2017 Salem Canal Investigation Summary Report* (AECOM and EHS Support, 2017). An additional monitoring event will be conducted in 2020 consistent with the MNR Framework to assess natural recovery processes in sediment and further support the ecological conceptual site model (ECSM) to ensure that conditions within the Former Seep Area of the Salem Canal remain protective of the environment.

1.0 Introduction

This *Revised Salem Canal Screening Level Ecological Risk Assessment* (Revised SLERA) was prepared on behalf of The Chemours Company (Chemours) for the Salem Canal at Chemours Chambers Works (the site) located in Deepwater, New Jersey (see Figure 1). Chemours assumed operations and environmental investigations at Chambers Works from E.I. du Pont de Nemours (DuPont) in 2015.

Environmental investigations have been conducted in the Salem Canal since August 2002 when, during drought conditions, magenta-colored water was observed seeping from the northern bank of the canal adjacent to the former Azo Dyes Manufacturing Area (see Figure 2). The observed seep was associated with a subsurface dense non-aqueous phase liquid (DNAPL) source within the Dye and White Products Areas of Concern (AOCs) located adjacent to the Salem Canal. Seep-related constituents, consisting primarily of chlorobenzene, dichlorobenzene, aniline, 4-chloroaniline, N-nitrosodiphenylamine, and benzene, migrated to sediment in the Salem Canal through the discharge of impacted groundwater in the seep area. Following the discovery of the seep, investigations were conducted to characterize the concentrations of seep-related constituents in environmental media (e.g., groundwater, sediment, pore water, surface water), identify sources and transport mechanisms of seep-related constituents, and support the selection of remedial alternatives.

A sheet-pile barrier (SBP) was installed in December 2008 (extended in 2012 and 2014) as an Interim Remedial Action (IRA) to prevent the migration of impacted groundwater into and underneath the Salem Canal. Following the installation of the sheet-pile barrier (SPB), investigation and monitoring of the conditions in the area where the seep formerly discharged (Former Seep Area) have continued to evaluate the effectiveness of the IRA for groundwater and the natural recovery processes in sediments, primarily biodegradation and burial (URS, 2013; AECOM and EHS Support, 2017). Studies conducted to date indicate the potential for natural recovery of sediments through multiple processes (URS, 2013; URS, 2015; AECOM and EHS Support, 2017). Based on these findings, the *Salem Canal Monitored Natural Recovery Framework Document* (MNR Framework) was developed to present an approach for evaluating monitored natural recovery (MNR) as a potential remedial alternative for sediment following the implementation of the groundwater remedial action (URS, 2015).

A SLERA was submitted to the U.S. Environmental Protection Agency (EPA) and New Jersey Department of Environmental Protection (NJDEP) in January 2015 to evaluate screening-level ecological risk associated with seep-related constituents in the Former Seep Area of the Salem Canal (2015 SLERA; AECOM, 2015). EPA requested that a SLERA be performed consistent with EPA *Ecological Risk Assessment for Superfund* (ERAGS; EPA, 1997) in a letter dated November 18, 2014 (received by DuPont on December 2, 2014). The SLERA expanded on the *2007 Dyes Area and White Products Area Baseline Ecological Evaluation* (BEE) and evaluated ecological risk based on groundwater data from adjacent areas of the facility, along with the sediment and surface water data collected from the Salem Canal [DuPont Corporate Remediation Group (CRG), 2007].

EPA and NJDEP comments on the 2015 SLERA were received on April 9, 2015 and April 28, 2015 (see Appendix A). A teleconference was convened between, EPA, NJDEP, and Chemours on June 23, 2015 to discuss the comments and proposed responses to select comments. During the June 23, 2015 teleconference, Chemours,

EPA, and NJDEP agreed that the SLERA would be revised based on EPA/NJDEP comments and additional analytical data for bulk sediment and pore water that were scheduled to be collected in the Former Seep Area in 2015 (URS, 2015; AECOM, 2015). In a letter dated July 10, 2015, Chemours provided responses to the April 9, 2015 and April 28, 2015 EPA/NJDEP comment letters and summarized agreements made with EPA/NJDEP during the June 23, 2015 teleconference (see Appendix A). Bulk sediment sampling to support the evaluation of the Former Seep Area was conducted in August 2015; pore water sampling in the Former Seep Area was conducted in January 2016 and August 2016 (AECOM and EHS Support, 2017).

EPA requested further characterization of sediment and surface water quality along the entire length of the Salem Canal adjacent to Chambers Works in a letter dated September 10, 2015. The purpose of the canal-wide characterization sampling was to evaluate whether surface water and sediment quality in the Salem Canal have been impacted by historical or current outfalls along the shoreline of Chambers Works (AECOM, 2016a). Sampling to support the canal-wide sediment and surface water investigation was completed in August 2016 (AECOM and EHS Support, 2017). Consistent with the additional bulk sediment and pore water data collected in 2015 in the former seep area, Chemours and EPA/NJDEP agreed to include the results of the 2016 canal-wide surface water and sediment characterization into the Revised SLERA to provide a more complete assessment of ecological risk for the Salem Canal adjacent to Chambers Works under current conditions. A Revised SLERA that incorporated the additional environmental data collected in 2015 and 2016 as well as EPA/NJDEP comments on the original SLERA was submitted in April 2017.

EPA and NJDEP comments on the April 2017 Revised SLERA were received on November 28, 2017 (see Appendix A). In addition to specific comments on the ecological risk assessment approach, EPA and NJDEP comments requested further evaluation of isolated areas of elevated concentrations that exceeded ESVs and representative background concentrations, particularly at specific stations adjacent to historical outfalls. In response to these comments, further sediment characterization sampling was conducted in December 2018 to define the extent of elevated concentrations in the identified isolated areas. In addition, surface water and pore water samples were collected in November 2018 to evaluate the potential groundwater discharge at the sediment-surface water interface at the eastern extent of the SPB. These additional sediment, pore water, and surface water data have been incorporated into this Revised SLERA to provide an updated characterization of ecological risk in the Salem Canal. In addition, EPA and NJDEP comments on the ecological risk assessment approach presented in the April 2017 Revised SLERA have also been addressed.

1.1 Scope and Objectives

The purpose of this Revised SLERA is to evaluate potential risks to ecological receptors exposed to site-related constituents under current conditions in the Salem Canal adjacent to Chambers Works.

The Revised SLERA evaluates potential risks to ecological receptors exposed to site-related constituents within the Salem Canal. Based on the phases of investigations

conducted in the Salem Canal, two potential exposure areas evaluated in the SLERA are as follows:

- Former Seep Area: Evaluation of exposure to seep-related constituents in environmental media within the Salem Canal that are associated with the historical discharge of impacted groundwater from the Dye and White Products AOCs located adjacent to the canal.
- Canal-Wide Area: Evaluation of exposure to potential site-related constituents, including metals, volatile organic constituents (VOCs), polycyclic aromatic hydrocarbons (PAHs) and other semi-volatile organic constituents (SVOCs), polychlorinated biphenyls (PCBs), and pesticides in environmental media that may be associated with site-related pathways outside of the Former Seep Area, including historical or current outfalls.

The Revised SLERA was conducted in accordance with EPA ERAGS (EPA, 1997). The scope of the Revised SLERA includes Steps 1 and 2 of the ERAGS guidance. Steps 1 and 2 were used to identify constituents of potential ecological concern (COPECs) in bulk sediment, sediment pore water, and surface water to support a scientific management decision point (SMDP) regarding the need for further risk characterization. ERAGS Section 3.2 was included to reduce uncertainty in the Revised SLERA conclusions and to refine the recommendations presented in the report. ERAGS Section 3.2 was used to refine the list of COPECs by (1) applying more representative exposure assumptions and (2) evaluating spatial and temporal patterns of the COPECs. ERAGS Section 3.2 focuses the Revised SLERA conclusions by identifying key COPECs and characterizing the spatial extent of potentially impacted sediments. In addition to EPA ERAGS, exposure evaluations were consistent with NJDEP *Ecological Evaluation Technical Guidance*, where applicable (NJDEP, 2018).

Specific objectives for each exposure area include the following:

- Identify COPECs in relevant exposure media, including bulk sediment, sediment pore water, and surface water.
- Identify ecological receptors that may be exposed to COPECs.
- Refine the list of COPECs using representative exposure assumptions.
- Recommend a SMDP regarding the need for further evaluation of ecological risk, if warranted.

1.2 Report Organization

The Revised SLERA is organized into the following sections:

- Section 2.0 presents the investigation background.
- Section 3.0 describes the environmental setting.
- Section 4.0 summarizes the screening-level problem formulation and effects evaluation.
- Section 5.0 describes the screening-level ecological exposure evaluation.
- Section 6.0 presents the screening-level exposure estimate and risk characterization.

- Section 7.0 presents the refined ecological exposure evaluation (ERAGS Section 3.2).
- Section 8.0 presents the refined exposure estimate and risk characterization (ERAGS Section 3.2).
- Section 9.0 presents the uncertainty analysis.
- Section 10.0 presents conclusions and recommendations.
- Section 11.0 lists the references cited in the Revised SLERA.

2.0 Investigation Background

This section provides a summary of previous investigations conducted in the Salem Canal. Additional detail regarding these investigations may be obtained in supporting investigation documents (DuPont CRG, 2006; DuPont CRG, 2007; URS, 2013; AECOM, 2015; AECOM and EHS Support, 2017).

2.1 Former Seep Area

The Salem Canal is a 200-foot wide freshwater channel that is impounded by the Munson Dam on the Chemours Chambers Works property. During drought conditions in August 2002, magenta-colored water was observed seeping from the northern bank of the canal into surface water. The seep was associated with the discharge of impacted groundwater from Dye and White Products AOCs located immediately adjacent to the northern bank of the canal; these AOCs were previously described in the *Preliminary Assessment Report (PAR)* and *Baseline Ecological Evaluation for Dyes and White Products Area* (DuPont CRG, 2006; DuPont CRG, 2007).

DuPont installed an emergency containment boom/silt curtain around the area of observed discoloration. Subsequently, various investigations were performed from 2002 through 2007 to:

- Characterize surface water, sediment, and B aquifer¹ groundwater quality.
- Identify the sources and transport mechanisms of seep-related constituents in groundwater, surface water, and sediment.
- Assess the potential impact of the seep-related constituents on potential human and ecological receptors.
- Evaluate and select potential remedial action(s).

Seep-related constituents were not detected above screening benchmarks in canal surface water outside of the silt curtain or downstream of the former seep area. The primary seep-related constituents identified in groundwater and sediment included chlorobenzene, dichlorobenzenes, aniline, 4-chloroaniline, n-nitrosodiphenylamine, and benzene. These constituents are related to a subsurface DNAPL source within the former Azo dyes manufacturing area, which is located to the north of the former seep area.

In December 2007, DuPont submitted the *Salem Canal Interim Remedial Action Work Plan (IRAWP)* (DuPont CRG, 2007) to the EPA and NJDEP, in which two remedies were proposed: installation of a SPB to prevent migration of the groundwater plume into and beneath the Salem Canal and a low-permeability sediment cap to minimize exposure (direct contact) of ecological receptors to the Salem Canal sediment. EPA and NJDEP approved the groundwater remedy (SPB) but requested reevaluation of the sediment remedy (EPA and NJDEP, 2008). A remedial alternative has not currently been accepted for sediment; however, numerous investigations have been completed to evaluate the feasibility of MNR as a sediment remedy for seep-related constituents (URS, 2013; URS, 2015; AECOM and EHS Support, 2017).

¹ The B aquifer is the shallow aquifer. The B aquifer consists of a sand layer (Upper B) overlying a sand and gravel layer (Lower B), which is laterally extensive and is bedded with sand lenses in some locations. Overall, the thickness of the B aquifer is approximately 15 feet to 20 feet (URS, 2013).

2.1.1 Summary of Previous Ecological Investigations

A BEE was completed in 2007 for the Dyes Area and White Products Area to evaluate the migration of COPECs in groundwater from the former manufacturing areas located immediately north of the canal (DuPont CRG, 2007). Consistent with NJDEP Technical Requirements for Site Remediation that were current in 2007, the objective of the BEE was to evaluate the co-occurrence of COPECs, environmentally sensitive areas (ESAs), and contaminant migration pathways to the identified ESAs.

The BEE concluded that there was the co-occurrence of ESAs, contaminant migration pathways, and COPECs within the area of concern associated with the Dyes Area and White Products AOCs. Complete contaminant migration pathways were identified from the area of concern to an adjacent segment of the Salem Canal. COPECs were identified through evaluation of sediment and surface water data from the potentially impacted area of the canal; these COPECs were also detected in groundwater from within the area of concern. COPECs were not identified in canal surface water outside of the former boom/silt curtain or downstream at potable water intake at the Munson Dam.

The BEE concluded that further investigation was warranted for the potentially impacted area of the Salem Canal. Direct contact ecological exposure pathways to bulk sediment were evaluated as part of an ecological exposure evaluation presented in the *Salem Canal Interim Remedial Action Work Plan* (IRAWP) to assess the protectiveness of the proposed capping remedy (DuPont CRG, 2007). The bulk sediment evaluation indicated limited potential for adverse effects to benthic invertebrate receptors resulting from exposure to seep-related constituents outside of the proposed sediment interim remedial measure (IRM) boundary, which included an approximately 58,000 square feet (approximately 1.3 acres) cap centered at the location of the seep. Outside of the sediment IRM boundary, COPEC concentrations were below no effect concentration sediment quality benchmarks (NEC SQBs) derived based on equilibrium partitioning (EqP) models and average total organic carbon (TOC) content in sediment (DuPont CRG, 2007). No further evaluation of potential direct contact exposure within the IRM boundary was conducted because it was assumed that the proposed cap would minimize exposure pathways to benthic receptors (DuPont CRG, 2007); however, concentrations of seep-related constituents exceeded NEC SQBs at some locations within the IRM boundary.

The overall findings of the 2007 BEE and IRAWP indicated that the potential for adverse ecological effects was negligible in surface water and the potential for adverse effects to bulk sediment were spatially-limited to a localized area adjacent to the observed seep.

2.1.2 Current Engineering and Institutional Controls

After the submittal of the IRAWP, engineering controls were implemented to address groundwater discharge to the canal. Specifically, engineering controls for groundwater discharge include the installation of a SPB and the existing Interceptor Well System² (IWS). Details regarding the IWS are described in the most recent semi-annual report of the New Jersey Pollutant Discharge Elimination System – Discharge to Groundwater

² The IWS has been in operation since 1970 to control the off-site migration of groundwater at Chambers Works. The IWS is a pump-and-treat system that recovers more than 1.5 million gallons of groundwater each day and transfers the groundwater to an on-site wastewater treatment plant. Treated water is then discharged to the Delaware River authorized under a NJPDES-DGW permit.

(NJPDES-DGW), which was submitted by Chemours to NJDEP in October 2016 (AECOM, 2016b).

An SPB was installed as a groundwater remedy to prevent the migration of impacted groundwater into and beneath the canal, i.e., source control. Installation of the initial 900-foot long by 28-foot deep section of SPB as the groundwater remedy was completed in December 2008; a 300-foot westward extension to the existing SPB was installed in early 2013. The SPB was further extended 200 feet westward in December 2014 and ultimately was extended northward to AOC 1 to encompass the entire western perimeter of the manufacturing area in late 2015 to early 2016.

Evaluations of groundwater data following the implementation of the groundwater remedial action for the Salem Canal concluded that the SPB is effective and is protective of the environment (URS, 2013; AECOM and EHS Support, 2017). The effectiveness of the SPB was evaluated with water-level data collected over a three-year period after installation (URS, 2013). Analyses indicated that the SPB is achieving its design purpose to redirect groundwater flow and prevent impacted groundwater migration to the canal surface water and sediment and downgradient groundwater. Specifically, groundwater levels behind the SPB have increased, and groundwater flow has been diverted away from the SPB and toward the IWS. Also, the groundwater plume south of the canal continues to reduce in size, and concentrations of COPECs are decreasing. Therefore, it was concluded that the SPB is effective and protective of the environment (URS, 2013; AECOM and EHS Support, 2017).

2.2 Canal-Wide Investigation

The 2016 Salem Canal-wide characterization sampling was requested by the EPA in a letter dated September 10, 2015, to provide additional characterization of potential site-related constituents in sediment and surface water within the Salem Canal adjacent to Chambers Works.

Previous investigations conducted within the Salem Canal largely focused on identifying the sources and transport mechanisms of seep-related constituents in groundwater, surface water, and sediment, within and surrounding the Former Seep Area. Sampling for other constituents (i.e., metals, PCBs) was limited within this area. The canal-wide characterization was conducted in August 2016 to provide additional characterization of potential site-related constituents in sediment and surface water outside of the former seep area, as well as non-seep related constituents within the Former Seep Area. Further sediment characterization sampling was conducted in December 2018 to define the extent of elevated concentrations in isolated areas identified adjacent to historical or current outfalls.

3.0 Environmental Setting

Located along the eastern shore of the Delaware River in Deepwater, New Jersey, the 1,455-acre Chemours Chambers Works Complex includes the active Chambers Works manufacturing area and the former Carneys Point Works (see Figure 1). The Salem Canal flows along the southern boundary of Chambers Works. Figure 2 identifies the study areas for the Salem Canal.

3.1 Habitat Description

The canal is a manmade canal approximately 10,000 feet long from Brown Dam on the Salem River to the mouth of the Salem Canal at the Delaware River. Adjacent to Chambers Works, the Salem Canal is approximately 200 feet wide and 5,200 feet long from the Route 130 bridge to the Delaware River. Munson Dam, which isolates the freshwater canal from the tidal influence of the Delaware River, is located approximately 1,100 feet upstream from the mouth of the Salem Canal at the Delaware River.

The Salem Canal was hand-excavated in 1872 to connect the tidal Salem River with the Delaware River and to allow commercial barge traffic from in-land agricultural areas to access commercial markets along the river. The canal was originally dredged to a depth of 12 to 14 feet below ground surface to an estimated elevation of -8 feet North American Vertical Datum (NAVD) 88. In 1933, DuPont acquired approximately 1,000 acres and riparian rights along a 12-mile stretch of the canal and Salem Creek to create a reservoir to supply freshwater to Chambers Works. The Munson Dam was constructed in 1933, isolating the freshwater portion of the canal with the brackish tidal water of the Delaware River.

A freshwater intake structure was constructed at the dam allowing DuPont to withdraw water for plant use. The plant intake at Munson Dam on the canal currently withdraws approximately 7 to 9 million gallons per day (mgd) from the canal, depending on needs, to be used as a freshwater supply for electricity production, fire suppression, process water, and potable water at Chambers Works.

The canal is a jurisdictional surface water body and is identified as an environmentally sensitive natural resource (ESNR), consistent with the definition provided in New Jersey Administrative Code (N.J.A.C.) 7:26E-1.8. Overall habitat quality in the segment of the Salem Canal within the Chambers Works property is degraded and of poor quality for aquatic and semi-aquatic receptors. There is no vegetated riparian zone associated with the canal. Facility roads, parking lots, or buildings extend to the top of the canal banks in most places, both on the northern and southern side. The adjacent terrestrial areas to the south of the Salem Canal are developed into parking lots with surrounding lawns that are mowed and maintained. The banks of the canal are steep and armored with concrete, asphalt, and aggregate rubble for shoreline protection on the northern side (see photographic log in Appendix A). The banks on the southern side of the canal are lined with invasive herbaceous vegetation, including *Phragmites australis* (common reed). There is little to no riparian vegetation to create a canopy for shade. The lack of shade likely results in high water temperatures and low dissolved oxygen, which may be additional ecological stressors during summer months. These cover types surrounding the Salem Canal result in poor quality habitat with limited value for wildlife.

Overall, the sediment surface is relatively flat and the thickness ranges from 3.5 to 4.5 feet in the middle of the canal and thins at the banks to an approximate thickness of 6 inches. In general, the sediment is gray to black silt with TOC content ranging from

approximately 0.2 to 14 percent and averaging approximately 2 percent for samples collected at surface depth intervals (0 to 0.5 feet; DuPont CRG, 2007). The lowest TOC content values were associated with sands collected from beneath the fine-grained, organic canal sediment layers.

Sedimentation within the canal has occurred since the completion of Munson Dam. A sedimentation evaluation based on radioisotope dating of two sediment cores during bulk sediment investigations in 2015 indicate that estimated linear accumulation rates (LAR) for sediments deposited within the last five years ranged from 1.3 centimeters per year (cm/year) to 1.6 cm/year (AECOM and EHS Support, 2017); these rates are greater than the 0.5 cm/year LAR that has been identified for sites where physical isolation may be an important natural recovery process for sediment (ITRC, 2014). These estimated sedimentation rates are representative of recent sediment accumulation in the Salem Canal that may be anticipated in the future if current conditions in the watershed remain consistent.

3.2 Potential Ecological Receptors

As described above, the segment of the canal adjacent to the site is a low-quality freshwater habitat. Stagnant flows due to the Munson Dam and highly organic sediment likely result in substantial physiochemical stressors in the canal with high temperatures and low dissolved oxygen during the summer. The lack of emergent vegetation or submerged aquatic vegetation limits habitat structure and diversity. Because of the physiochemical stressors and a lack of habitat structure, the Salem Canal is expected to support tolerant communities of benthic invertebrates and fish. Wildlife receptors, including semi-aquatic birds and mammals, may opportunistically forage within the Salem Canal; however, the lack of established riparian habitat likely limits its use as exclusive foraging habitat.

4.0 Screening-Level Problem Formulation and Effects Evaluation

This section presents a screening-level problem formulation to guide the risk evaluation process for the Salem Canal (EPA, 1997). The screening-level problem formulation develops a conceptual model for exposure at the site that addresses the following:

- Defines ecological exposure areas for assessment in the screening-level exposure evaluation based on existing data and site understanding (see Section 4.1).
- Identifies potential source areas and complete migration pathways from potential source areas to ecological exposure media within the Salem Canal (see Section 4.2).
- Identifies COPECs that are known or suspected to exist in source areas and migration pathways that may be present in exposure media within the Salem Canal (see Section 4.3).
- Describes fate and transport characteristics of known or suspected COPECs that may exist within the identified exposure areas (see Section 4.4).
- Describes the mechanisms of ecotoxicity associated with known or suspected COPECs to guide the selection of receptors and assessment endpoints (see Section 4.5)
- Identifies likely ecological receptors of concern and potentially complete exposure pathways, including primary ecological exposure routes (see Section 4.6).
- Defines assessment endpoints for the screening-level exposure evaluation and specific measurement endpoints to evaluate assessment endpoints (see Section 4.7).
- Presents a screening-level effects evaluation to establish screening-level benchmarks to assess the potential for adverse ecological effects (see Section 4.8).

Key elements of the ecological conceptual site model (ECSM) for potential source areas and complete migration/exposure pathways for ecological receptors are illustrated in Figure 3 for constituents known or suspected to exist in the Salem Canal. The following subsections define the exposure areas and describe key elements of the ECSM and SLERA problem formulation described above, including assessment endpoints and measurement endpoints identified for primary ecological exposure pathways and receptors.

4.1 Exposure Areas

Based on the phases of investigations conducted to date, ecological exposure in the Salem Canal is assessed in the SLERA for two primary exposure areas: Former Seep Area and Canal-Wide Area (see Figure 2):

- Former Seep Area: As illustrated in Figure 4, the Former Seep Area within the Salem Canal consists of an approximately 120-foot x 500-foot area adjacent to the northern bank of the Salem Canal where seep-related constituents exceeded sediment quality benchmarks in previous investigations (URS, 2015).

- Canal-Wide Area: The Canal-Wide Area includes the area of the Salem Canal adjacent to Chambers Works that is outside of the Former Seep Area. The extent of the Canal-Wide Area was further divided into three sub-reaches for the evaluation as illustrated in Figure 2:
 - Reach 1: Consists of the eastern portion of Salem Canal from the site boundary at the railroad bridge west to the beginning of the SPB on the northern bank. Sediment and surface water investigations had not been previously conducted within this reach.
 - Reach 2: This reach spans the length of the SPB to Munson Dam and includes the Former Seep Area where extensive historical sediment sampling focused on the release of seep-related organic constituents.
 - Tidal Reach: The portion of Salem Canal downstream of Munson Dam is hydrologically connected to the Delaware River and can be characterized as a tidal, mesohaline waterbody. Prior to 2016, sediment and surface water investigations had not been conducted within the Tidal Reach.

4.2 Potential Source Areas and Complete Migration Pathways

The following subsections describe complete migration pathways identified from the site to the exposure areas identified in the Salem Canal. A migration pathway is the pathway by which a constituent may travel from a site-related source area to the exposure areas describe in the preceding section.

4.2.1 Former Seep Area

Prior to the installation of the SPB, the migration of impacted groundwater from a source area within an AOC in the manufacturing area was the primary source and transport pathway for constituents in the Former Seep Area. As previously discussed in Section 2.1, groundwater impacted by a subsurface DNAPL source within the Dye and White Products AOCs historically discharged to the Salem Canal sediment and surface water. The installation of the SPB to prevent the discharge of impacted groundwater from the source area within the Dye and White Products AOC effectively eliminated this migration pathway to surface water and sediment in the Salem Canal (see Section 2.1.2). Constituents currently present in sediment within the Former Seep Area resulted from groundwater historically discharging directly to surface water and sediment through the sidewall of the canal and diffusion upward through canal sediment.

4.2.2 Canal-Wide Area

Potential sources of constituents to the Canal-Wide Area include AOCs associated with the manufacturing area of Chambers Works, as well as potential regional sources upstream of the site. The primary conceptual migration pathways from the site to areas outside of the Former Seep Area include surface discharge from historical or active outfalls that may have conveyed process or stormwater from the manufacturing area to the Salem Canal. An inventory of outfalls identified along the length of the Salem Canal is presented in Table 1. Groundwater discharge may have been an historical migration pathway in some portions of the Canal-Wide Area; however, the installation of the SPB along most of the shoreline of the Salem Canal Study Area has effectively eliminated this pathway. Localized atmospheric deposition and transport to the Salem Canal via stormwater outfalls also represents a potentially complete pathway.

Downstream transport from potential sources on the Salem Canal upstream of the site may also contribute to constituents in exposure media within the site reaches of the Canal-Wide Area. The Salem Canal receives water flow from the Salem River that has a drainage area of approximately 60 square miles; 40 percent of the entire Salem River watershed is categorized as agricultural. Agricultural use in the watershed upstream of Chambers Works may contribute pesticides, metals, and other constituent groups to surface water and sediment in the Salem Canal. Transportation infrastructure is an additional source of constituents immediately upstream of the site. Surface transportation infrastructure associated with Route 130 near the site boundary and the Interstate 295 (I-295) interchange located approximately 2,000 feet upstream of the Route 130 bridge contribute constituents associated with motor vehicles via stormwater and atmospheric pathways. Constituent groups that may be associated with surface transportation infrastructure include metals (e.g., cadmium, lead, zinc), PAHs, benzene/toluene, ethylbenzene/xylenes (BTEX), and PCBs. Background sampling was conducted in the Reference Reach upstream of the site to characterize potential contributions from upstream agricultural, transportation infrastructure and other regional sources within the watershed. Potential sources upstream of the site are considered since regional anthropogenic sources upstream of the site may contribute to these constituent groups in site reaches within the Canal-Wide Area.

Conceptual migration pathways from potential sources to the Canal-Wide Area are summarized by reach:

- Reach 1: Active or historical site outfalls are present within this reach of the canal; however, based on the conceptual site model for groundwater, groundwater discharges to this reach are not expected (URS, 2013).
- Reach 2: Prior to the construction of the SPB, groundwater discharged to Salem Canal in this reach (URS, 2013). Site outfalls were abandoned in this reach prior to the installation of the SPB.
- Tidal Reach: The portion of Salem Canal downstream of Munson Dam is hydrologically connected to the Delaware River. Because of its tidal connection, surface water and sediment transport dynamics in this reach are functionally different than those of the impounded portion of Salem Canal. Sediment and surface water quality in the Tidal Reach are influenced by regional and anthropogenic conditions in the Delaware River. Potential migration pathways from the site to the Tidal Reach include discharge from active or historical outfalls. However, site outfalls were abandoned in this reach prior to the installation of the SPB, with the exception of stormwater outfalls (Table 1).
- Reference Reach: Downstream surface water transport and regional atmospheric deposition are predominant migration pathways from potential source areas to the Salem Canal. Particulate-bound constituents may be mobilized from agricultural and transportation infrastructure sources through surface runoff of stormwater. Constituents may also be transported from this source areas via atmospheric deposition directly to the Salem Canal or the ground surface where surface pathways via stormwater runoff may ultimately transport constituents to the Salem Canal.

4.3 Constituents of Potential Ecological Concern

This section describes constituents that may be identified as COPECs in exposure media within the exposure areas identified in the Salem Canal based on the known or suspected presence of these constituents in source areas or along migration pathways identified in the previous section.

In the Former Seep Area, COPECs for sediment, groundwater, and surface water were previously determined by evaluating constituent concentrations with applicable ecological screening values (DuPont CRG, 2007). Groundwater data were compared to New Jersey Class IIA groundwater standards (GWIIA) to conservatively identify constituents in groundwater discharge that may potentially migrate to surface water where exposure pathways to ecological receptors may be complete. Sediment concentrations were compared to SQB values that were presented in the NJDEP-approved Salem Canal Pre-Design Investigation Work Plan (DuPont CRG, 2005). Surface water samples were compared to ecological screening criteria based on either Tier II secondary chronic values (SCVs) (EPA, 1993a) or the criteria calculated for site-specific compounds [Solid Waste Management Unit (SWMU) 5 Technical Memo (DuPont CRG, 1999)], depending on which criterion was more stringent.

The results of previous screening evaluations in the Former Seep Area indicate that COPECs known or suspected to be associated with the historical discharge of impacted groundwater include predominately VOCs, specifically chlorobenzene, dichlorobenzenes (1,2-dichlorobenzene, 1,3-dichlorobenzene, and 1,4-dichlorobenzene), benzene, trichlorobenzene. In addition to VOCs, several SVOCs were associated with impacted groundwater in the source area. Predominant SVOCs that are known or suspected COPECs in the Former Seep Area include aniline, 4-chloroaniline, n-nitrosodiphenylamine, o-toluidine, and PAHs.

Outside of the Former Seep Area, sediment and surface water data were limited in the Salem Canal, and no background data were available for the upstream Reference Reach. As discussed in the previous section regarding potential source areas and migration pathways, suspected COPECs in the Canal-Wide Area may include metals, VOCs, SVOCs including PAHs, PCBs, and pesticides. As discussed in Section 4.2.2, the presence some of these COPEC groups in site reaches, including metals, pesticides, and PCBs, may be associated with migration pathways from source areas upstream of the site.

4.4 Fate and Transport Characteristics

Environmental fate and transport characteristics for known or suspected COPEC groups identified in the Salem Canal are described in the following subsections.

4.4.1 Sediment

Potentially complete migration pathways of site-related COPECs identified in Section 4.3 are dependent on fate and transport characteristics of constituent groups. The chemical transformation of seep-related VOC and SVOCs through biodegradation has been documented as an important fate process in a literature review, laboratory studies using Salem Canal sediment, and field studies of potential biodegradation in site-specific groundwater and pore water samples (URS, 2013; URS, 2015; AECOM and EHS Support, 2017).

In addition to biodegradation, burial of COPECs in sediment depths below the biologically active zone (BAZ) may be an important natural recovery process in sediments in Reach 1 and Reach 2 upstream of Munson Dam. As discussed in Section 3.1, a sedimentation evaluation estimated linear accumulation rates for sediments deposited within the last five years ranging from 1.3 cm/year to 1.6 cm/year (AECOM and EHS Support, 2017), which is 2 to 3 times greater than the rate that has been identified for sites where physical isolation may be an important natural recovery process for sediment (0.5 cm/year LAR; ITRC, 2014). The following subsections summarize information regarding the fate and transport characteristics of primary COPEC groups identified in the Salem Canal.

Volatile and Semi-Volatile Organic Constituents

Research describing the fate and transport of VOC and SVOCs in sediments are presented in detail in Appendix C of the *Salem Canal Groundwater Remedial Action Progress and Sediment Investigation Status Report* (URS, 2013). Additional information regarding the fate of VOCs and SVOCs in sediments within the Salem Canal are provided in the *2017 Salem Canal Investigation Summary Report* (AECOM and EHS Support, 2017).

Overall, research studies indicate that conditions in sediments within the Salem Canal have the potential for anaerobic dechlorination of chlorinated benzenes to an endproduct of methane. The findings also indicate that while low levels of chlorobenzene may persist, dichlorobenzene and benzene are degradable to concentrations below detection limits under anaerobic conditions.

Most of the sediment COPECs are known to readily biodegrade in the presence of oxygen. Site-specific studies indicate that shallow sediment at the sediment/water interface (SWI) contains an abundance of aerobic chlorobenzene degrading bacteria. Given sufficient oxygen, degradation at the SWI could result in complete mineralization of chlorobenzene within the upper 2 to 3 millimeters (mm) of sediment (see URS, 2013; and Kurt et al., 2012).

Former dye chemicals, aniline, and 4-chloroaniline [or p-chloroaniline (PCA)], have been documented to biotransform under aerobic conditions; however, their fate under anaerobic or reduced conditions was less well understood. Biological microcosms with aquifer material and sediment were established under aerobic, Fe (III)-reducing, nitrate-reducing, sulfate-reducing, and methanogenic conditions. Aniline was degraded anaerobically under nitrate-reducing, iron-reducing, sulfate-reducing, and methanogenic conditions. PCA was degraded under nitrate-reducing conditions. Investigation of aniline and PCA degradation pathways and further characterization of the microbial community are described in URS (2013), Li et al. (2008a), and Li et al. (2008b).

Metals

Fate and transport processes are important in controlling the distribution of metals discharged to the aquatic environment. In aquatic systems, metals are distributed between the dissolved and particulate phases. Dissolved metal ions are the most available for biological uptake and the most toxic metal form (John and Leventhal, 1995). However, under circumneutral pH conditions found in most natural waters, metals are primarily complexed by colloids or bound to particulates (Morel and Hering, 1993).

Particulate-bound metals in surface water are deposited in sediments in low-energy environments such as the Salem Canal upstream of Munson Dam. Sediment metals may partition to pore water, colloidal material, ligands, or the mineral matrix. The labile

pool of metals in sediment is subject to speciation in the aqueous phase within pore water and sorption to solid phases (EPA, 2007a). In pore water, metals will react or bind with ligands in accordance with the pH, redox, ionic strength, and abundance of the ligands (EPA, 2007a).

Pesticides

The fate and transport of pesticides in aquatic environments varies considerably depending on the physical and chemical properties of the compound. These properties determine whether the pesticide quickly breaks down, adsorbs strongly to suspended solids and sediments, diffuses into the water column, or rapidly volatilizes to the air. Persistence in the environment depends on how quickly the pesticide degrades, which is largely a function of its chemical composition and environmental conditions. Pesticides are degraded by chemical and biological processes, such as photochemical degradation, hydrolysis, oxidation, reduction, and microbial decay (Reese et al., 1972; WHO, 1986; Helfrich et al., 2009).

PCBs

PCBs are a group of 209 synthetic halogenated aromatic hydrocarbons that have been used extensively in the electricity generating industry as insulating or cooling agents in transformers and capacitors (Eisler, 1986). The fate and transport of PCBs in aquatic environments are influenced by varying physical, chemical, and biological processes and are largely dependent on the location and degree of chlorination of the biphenyl molecule. In general, when PCBs, particularly the higher chlorinated congeners, are introduced into aquatic environments they tend to adsorb strongly to suspended solids and sediments, especially those high in organic carbon [World Health Organization (WHO), 1993; Agency for Toxic Substances and Disease Registry (ATSDR), 2000; Canadian Council of Ministers of the Environment (CCME), 2009]. Although adsorption in sediment can immobilize PCBs for relatively long periods, de-sorption into the water column may occur by both abiotic and biotic routes. Sediments can therefore act as both an environmental sink and reservoir of PCBs for organisms (WHO, 1993).

4.4.2 Groundwater

Site-specific field studies have been conducted to evaluate the biodegradation of seep-related constituents in collected groundwater samples including the following:

- Application of natural abundance Carbon-13 (^{13}C) to evaluate the biodegradation of chlorinated benzenes in groundwater (URS, 2013; Sherwood-Lollar et al., 2012).
- Molecular analysis of the planktonic and surface associated microbial community in the B aquifer (URS, 2013).

Compound specific isotope analyses (CSIA) was used to assess the biodegradation of 1,2,4- trichlorobenzene (TCB), dichlorobenzene, chlorobenzene, and benzene in groundwater samples collected from wells in the former seep area (including samples beneath the Salem Canal sediments). The results of the study indicate that the spatial and temporal patterns of carbon isotope enrichment in 1,2-dichlorobenzene, 1,4-dichlorobenzene, and 1,2,4-TCB are consistent with *in situ* biodegradation under anaerobic conditions at the site.

A field study was also conducted to evaluate the distribution and abundance of microbial biomass that could potentially support COPEC biodegradation. The data indicate that

the different groundwater environments in the Salem Canal have different microbial populations that are capable of degrading complex organic compounds (including dichlorobenzene) and are highly adaptable to changing environmental conditions. Organisms were consistent with a community of organisms from anoxic and reducing environments. Other microbes identified included sulfur-reducing and metal-transforming species (see URS, 2013).

4.5 Aquatic Ecotoxicity

This section summarizes the bioaccumulation potential, fish bioconcentration factors (BCFs), and general ecotoxicological effects associated with COPECs. The objectives of this evaluation are to assess the following:

- The potential ecotoxicity of COPECs
- The potential for ecological receptors in upper trophic levels including birds and mammals to be exposed to COPECs

4.5.1 Bioaccumulation

Bioaccumulation is the incorporation of COPECs from environmental media into biological tissues. The following subsections provide a brief overview of the bioaccumulation potential of COPEC groups that may be present in exposure media within the Salem Canal.

Volatile and Semi-Volatile Organic Compounds

An evaluation of the chemical characteristics of volatile and semi-volatile COPECs indicates limited potential for bioaccumulation and, therefore, limited potential for exposure to upper trophic wildlife receptors through bioaccumulation and ingestion pathways. The purpose of evaluating bioaccumulation potential is to describe the potential of the COPECs to bioaccumulate in tissues and potentially exert a toxic effect and/or expose upper trophic wildlife receptors through ingestion pathways.

COPEC bioaccumulation can be estimated based on the log n-octanol/water partitioning Coefficient ($\log K_{ow}$). The primary source for $\log K_{ow}$ values was the eChemPortal, which was developed by the Organization for Economic Co-operation and Development (OECD). Constituents with $\log K_{ow}$ values greater than 3.5 are considered to be bioaccumulative; that is, they are likely to partition into organic materials, including the lipids of organisms (EPA, 2000). Generally, bioaccumulation is likely to occur with persistent and very hydrophobic chemicals including those chemicals with $\log K_{ow}$ values that range from 5 to 8 (Hoffman et al., 1995).

As indicated in the table below, published values for K_{ow} for COPECs identified in Section 4.3 are lower than 3.5 for most compounds, indicating limited potential for bioaccumulation. Because of the low potential for bioaccumulation, it is also unlikely that these compounds would exhibit the potential for a toxic effect or accumulate in prey tissues that may be consumed by upper trophic wildlife receptors.

Constituent	$\log K_{ow}$	Reference	Potentially Bioaccumulative Compound?
Chlorobenzene	2.84	Lu et al., 2000	No
1,2-Dichlorobenzene	3.43	OECD SIDS, 2001	No
1,4-Dichlorobenzene	3.44	EPA, 2014a	No
Aniline	0.9	Lide, 2002	No

Constituent	log K _{ow}	Reference	Potentially Bioaccumulative Compound?
4-Chloroaniline	1.83 to 2.05	Boehncke et al., 2003	No
n-Nitrosodiphenylamine	2.57 to 3.13	ATSDR, 1989.	No
Benzene	2.13	EPA, 2014b	No
o-Toluidine	1.40	OECD SIDS, 2004	No
1,2,4-Trichlorobenzene	4.02	ATSDR, 2010	Yes
1-Naphthylamine	2.25	Hansch, Leo & Hoekman 1995.	No
PAHs	6.04 ^A	EPA, 2009a	Yes

Notes: A. value for benzo(a)pyrene presented.

Bioaccumulation pathways are not likely to be significant for the only COPECs with log K_{ow} values greater than 3.5 (1,2,4-TCB and PAHs). Although present in canal sediment, the concentrations of the SVOC 1,2,4-TCB do not exceed no-effect sediment benchmarks that are considered protective of aquatic life. Higher trophic level organisms, including birds and mammals, can metabolize PAHs and eliminate the by-products; therefore, transfer to upper trophic wildlife receptors is anticipated to be minimal. Specifically, unsubstituted PAHs do not accumulate in fish adipose tissues, despite their high lipid solubility, because they are quickly metabolized (Eisler, 1987); aquatic invertebrate communities do not metabolize PAHs as readily and may have some potential to bioaccumulate.

Metals

The availability of metals to be incorporated into biological tissues does not necessarily correspond with the total concentration of metals in sediment or surface water; bioavailability is directly related to the speciation of metals. For most divalent metals, the most bioavailable and toxic forms of metals are the metal ions or small metal-anion complexes, which are present at very low concentrations in the environment. Most metals in sediment are not available for uptake due to strong complexation by solid phases. For example, metals precipitated as metal-sulfide ligands may be resistant to solubilization under typical geochemical conditions observed in sediment or sediment pore water (Sigg and Behra, 2005). Mercury bioaccumulation is increased by the methylation of inorganic forms of mercury into methylmercury, an organic form that is more bioavailable and has been demonstrated to biomagnify with increasing trophic levels (i.e., concentrations increase with increasing trophic levels).

Pesticides

Two key properties of pesticides that control their bioaccumulation in aquatic biota are hydrophobicity and persistence. Compounds that break down slowly and are persistent in the environment are generally more bioaccumulative. Pesticides are accumulated in body tissues, especially fats, of aquatic organisms either directly through ingestion or absorption of contaminated water or indirectly by consumption of contaminated food or sediment.

PCBs

The primary ecological concern over PCBs is their high bioaccumulation capacity due to their high lipid solubility and slow rate of metabolism and elimination. There are multiple mechanisms influencing the bioaccumulation of PCBs in aquatic biota. These mechanisms can include direct uptake from the water column across gills or epidermis (i.e., bioconcentration), direct contact with contaminated sediments, and consumption of contaminated food or sediment (WHO, 1993). Due to their extremely high liposolubility,

PCBs have been shown to biomagnify with increasing trophic levels within the food chain (Eisler, 1986).

4.5.2 Ecotoxicity

This section summarizes information regarding the ecotoxicity of COPECs in canal sediment, pore water, and surface water. The general mode of toxicity for VOC/SVOCs and PAHs is presented below.

Volatile and Semi-Volatile Organic Constituents

Many of the Tier 2 Equilibrium Partitioning Sediment Benchmark (ESB) nonionic organic chemicals identified by EPA (2008), such as key seep-related COPECs including chlorobenzene, are considered to be narcotic (EPA, 2008). The primary mode of toxicity for benthic invertebrates exposed to narcotic chemicals is narcosis, which results in the degradation of cell membranes (Burgess, 2009).

Chlorobenzene is moderately toxic to aquatic organisms with toxicity generally occurring within the >1,000 micrograms per liter ($\mu\text{g/L}$) to 100,000 $\mu\text{g/L}$ range (EPA, 1995a). A 96- to 98-hour no observed effect concentration (NOEC) reported for sediment-dwelling organisms including *Chironomus thummi* (midge) was 720 $\mu\text{g/L}$ (van der Zandt et al., 1994). The chronic toxicity value used to derive the Tier 2 ESB for chlorobenzene published in *Procedures for the Derivation of Equilibrium Partitioning Sediment Benchmarks (ESBs) for the Protection of Benthic Organisms: Compendium of Tier 2 Values for Nonionic Organics* is 880 $\mu\text{g/L}$ (EPA, 2008). These values support the chronic aqueous benchmark value of 1,003 $\mu\text{g/L}$ derived for chlorobenzene in the development of sediment benchmarks for the Salem Canal (DuPont CRG, 2005). Acute toxicity data for chlorobenzene obtained from studies of the warmwater fish species *Lepomis macrochirus* (bluegill) yielded a 96-hour LC_{50} value for juveniles that ranged from 4,500 $\mu\text{g/L}$ (Bailey et al., 1985) to 16,000 $\mu\text{g/L}$ (Buccafusco et al., 1981).

As previously discussed, VOCs do not bioaccumulate to any significant degree; therefore, they do not generally pose a risk to environmental receptors via trophic transfer to wildlife receptors. Because of the low potential to bioaccumulate, it is also not expected that chronic adverse ecological effects would be expected for benthic invertebrates. Due to the low potential to bioconcentrate and the absence of these compounds from canal surface water, fish are also not expected to be adversely affected by VOCs.

PAHs occur in the environment as complex mixtures (Burgess, 2009) and are considered Type I narcotic chemicals (Verhaar et al., 1992). The predominant mechanism of PAH toxicity to invertebrates is narcosis, which results in the alteration of cell membrane function, which can then result in mild toxic effects or mortality depending upon the duration and intensity of the exposure (Burgess, 2009). The potential effects of PAH-induced narcosis on benthic invertebrate communities can include decreased abundance, diversity, and growth (Environment Canada, 1999).

The direct contact toxicity of PAHs is additive and predicted more accurately by dissolved concentration in pore water when compared to bulk sediment samples (EPA, 2003a; Di Toro et al. 1991). Dissolved PAH constituents in sediment pore water represent the bioavailable and more toxic phase (DiToro et al., 1991). It is widely recognized that pore water concentrations more accurately predict observed community level effects than do bulk sediment concentrations for nonionic compounds (NJDEP, 2018). Based on the additive toxicity of PAHs in pore water and the occurrence of PAHs

as mixtures in the environment, EPA guidance recommends the evaluation of direct contact toxicity of PAH mixtures based on the sum of toxic units (TUs) for individual PAHs estimated in pore water using EqP (EPA, 2003a).

Metals

The soluble phase of metal ions in sediment pore water is generally the most bioavailable and potentially toxic form to ecological receptors. As a result, the bioavailability and toxicity of metals in sediments is correlated with the fraction of metals in sediment pore water rather than total metal concentrations in bulk sediment (EPA, 2007a; EPA, 2005a; Di Toro et al., 2005; Ankley et al., 2006; Hansen et al., 1996; Ankley et al., 1991; Di Toro et al., 1992; and Luoma, 1989). Most metals in pore water are complexed by colloids and do not exist as freely dissolved metal – ion complexes (Burgess et al., 1996). Sulfide is an important control on metal bioavailability and toxicity (Burton, 2010; EPA, 2007a; EPA, 2005a). In the aerobic portion of the sediment, dissolved and exchangeable metals are efficiently scavenged by iron and manganese oxides, thereby limiting the bioavailability and toxicity of metals (DiToro et al., 1990). In addition to redox, pH controls metal speciation and binding by affecting the species distribution of dissolved ligands and the surface charge of binding sites (EPA, 2007). Generally, metal mobility, and associated toxicity, increases at low pH and decreases as pH increases, at which point greater sorption occurs (EPA, 2007a).

Pesticides

The toxicological effects of pesticides are a function of toxicity, exposure time, dose rate, and persistence in the environment and can range from acute effects, such as immediate fish kills, to chronic effects that may affect the vitality of developing larvae or impair reproduction (Reese et al., 1972; WHO, 1986). The chemical degradation products of certain pesticides may be more toxic than the parent compounds.

PCBs

The presence of PCBs in biological organisms at elevated concentrations has been associated with reproductive failure, birth defects, skin lesions, tumors, liver disorders, and, among sensitive species, death (Eisler, 1986). Ecological exposure to PCBs is primarily an issue of bioaccumulation rather than direct toxicity (see Section 4.5.1). The toxicological properties of PCBs are influenced primarily by the partitioning coefficient based on solubility in N-octanol/water (K_{ow}) and steric factors, resulting from different patterns of chlorine substitution. Typically, PCB isomers with high K_{ow} values, and high numbers of substituted chlorines in adjacent positions, constitute the greatest environmental concern (Eisler, 1986).

4.6 Receptors of Concern and Primary Exposure Routes

Receptors of concern identified for evaluation in the SLERA include the following:

- Benthic invertebrates
- Fish
- Wildlife: Semi-aquatic birds and mammals

The following subsections discuss primary exposure routes for receptors groups that may be exposed to COPECs in the Salem Canal.

4.6.1 Benthic Invertebrates

Exposure routes for benthic invertebrates include the following:

- Bulk sediment: direct contact/absorption within the BAZ; direct/incidental ingestion
- Sediment pore water: direct contact/absorption within BAZ

Benthic invertebrates are the most susceptible to the effects of sediment-related COPECs because of their sedentary nature and direct exposure to sediment and sediment pore water. Because of this exposure, benthic invertebrates are sensitive to both acute and chronic changes in sediment quality. For benthic invertebrates, exposure occurs within the BAZ of sediment, which operationally extends from the sediment-surface water interface (SWI) to a depth of approximately 0.5 feet (6 inches) for freshwater sediment (EPA, 2005b; EPA, 2015). In environments similar to the Salem Canal with highly organic, fine-grained sediments and limited flow, the BAZ often does not extend as deep as 0.5 feet due to oxygen depletion in reducing sediment (EPA, 2005b; EPA, 2015). However, the BAZ was considered to extend from 0 to 0.5 feet below the SWI for the purposes of the conservative screening-level exposure evaluation.

Direct contact exposure to COPECs in pore water is a more relevant exposure route for benthic invertebrates when compared to bulk sediment exposure. Numerous studies indicate that pore water concentrations are a better predictor of constituent bioavailability and toxicity to benthic invertebrate receptors when compared to bulk sediment concentrations (EPA, 2005a; EPA, 2003a; NJDEP, 2018; Parkerton and Maruya, 2013). The bioavailability and toxicity of COPECs in sediment are influenced by sediment physiochemical characteristics, including the quantity and type of organic carbon, which affects the partitioning of constituents between sediment and pore water. Site-specific measurements of freely dissolved concentrations in sediment pore water (C_{free}) are the most direct indicator of constituent bioavailability and partitioning when compared to other approaches to estimate C_{free} in pore water, including EqP models from bulk sediment (Department of Defense, 2009; Parkerton and Maruya, 2013).

4.6.2 Fish

Fish were selected as receptors of concern because of continuous contact with surface water. Direct contact/absorption of surface water is the primary exposure route for fish evaluated in the SLERA. Demersal fish may also be exposed to COPECs through the direct ingestion of sediment-associated prey and the incidental ingestion of sediment and pore water while foraging in sediment.

4.6.3 Wildlife

The Salem Canal adjacent to Chambers Works provides limited wildlife habitat due to the lack of riparian vegetation and cover along the developed shoreline of the facility. However, semi-aquatic birds and mammals may opportunistically forage within the Salem Canal. Representative species are used in the Revised SLERA to evaluate potential exposure to semi-aquatic wildlife receptors include:

- Omnivorous bird: Mallard (*Anas platyrhynchos*)
- Piscivorous bird: Great blue heron (*Ardea herodias*)
- Omnivorous mammal: Raccoon (*Procyon lotor*)

These representative wildlife receptors may be exposed to bioaccumulative COPECs through the following primary exposure routes:

- Dietary items: Direct ingestion
- Bulk sediment: Incidental ingestion

Wildlife may also be exposed through the direct and incidental ingestion of surface water from the Salem Canal. However, this exposure route provides a negligible contribution to the total receptor dose when compared to the direct ingestion of dietary items and the incidental ingestion of bulk sediment. Wildlife ingestion of surface water is not an exposure route that is quantitatively evaluated in the Revised SLERA.

4.7 Assessment and Measurement Endpoints

Assessment endpoints are explicit expressions of environmental values to be protected (EPA, 1998). Measurement endpoints represent measurable responses to a stressor that are related to the values specified as assessment endpoints (EPA, 1992).

Table 2 identifies the assessment endpoints and associated measurement endpoints selected for the exposure areas identified in the SLERA. Given the limited size of the exposure area, the survival, growth, and reproduction of benthic community is the only assessment endpoint identified for the Former Seep Area. Assessment endpoints identified for the protection of the survival, growth, and reproduction of the fish community and semi-aquatic wildlife populations were identified for the Canal-Wide Area due to the broader foraging ranges of these receptor groups. However, sediment and surface water data collected from within the Former Seep Area are included in the calculation of exposure point concentrations (EPCs) used in the measurement endpoints to evaluate fish and wildlife assessment endpoints.

The benthic invertebrate community assessment endpoint is evaluated using a weight-of-evidence approach that considers the relevance of each measurement endpoint in estimating the bioavailability and toxicity of COPECs. As discussed in Section 4.5.2, pore water concentrations are a better predictor of constituent bioavailability and toxicity to benthic invertebrate receptors when compared to bulk sediment concentrations (EPA, 2005a; EPA, 2003a; NJDEP, 2018; Parkerton and Maruya, 2013). Therefore, the measurement endpoint evaluating pore water exposure is afforded greater weight in estimating exposure and characterizing risk to benthic invertebrates, relative to measurement endpoints based on bulk sediment concentrations.

4.8 Screening-Level Effects Evaluation

The screening-level effects evaluation establishes constituent exposure concentrations that represent benchmarks to assess the potential for adverse effects. The following subsections discuss the conservative screening criteria established for the selection of COPECs and additional receptor-specific ecotoxicological data that may be used in exposure estimation and risk characterization. Benchmarks representing NOECs were used preferentially. The following subsections identify the hierarchy of ecological screening values (ESVs) that were used to evaluate COPEC exposure from relevant media.

4.8.1 Sediment

The screening of site-related constituents in sediment included a quantitative assessment of direct contact toxicity effects to benthic invertebrates consistent with the ECSM presented above. Sediment ESVs used in the screening-level exposure evaluation are summarized in Table 3. The following sources were used in the selection of ESVs for sediment:

- NJDEP (2009): Freshwater Criteria Lowest Effects Levels (LELs)
- MacDonald et al. (2000): Consensus-based sediment quality guidelines for freshwater ecosystems
- EPA (2003b): Region 5 Ecological Screening Levels (Sediment)
- EPA (2006): EPA Region 3 Biological Technical Assistance Group (BTAG) Freshwater Benchmarks
- Washington State No Effect Level (NEL) Sediment Quality Standards
- Calculated ESVs based on an EqP model (DuPont CRG, 1999).

4.8.2 Surface Water

Separate ESVs were derived to evaluate surface water data in freshwater reaches (Reach 1 and Reach 2) and the Tidal Reach, as summarized in Table 4 and Table 5, respectfully. Surface water ESVs were derived separately for these reaches due to the differences in hardness values that affect the calculation of hardness-dependent criteria for metals. Average hardness values calculated from surface water samples collected from freshwater [85.2 milligrams per liter (mg/L) as CaCO₃] and tidal (440 mg/L as CaCO₃) reaches were used in the calculation of hardness-dependent metals criteria. ESVs for surface water were identified from the following hierarchy of screening criteria/benchmarks:

- NJDEP (2009): Freshwater (FW2) Chronic Aquatic Criteria
- NJDEP (2016): NJDEP Surface Water Quality Standards
- EPA (2009b): National Recommended Water Quality Criteria (NRWQC)
- EPA (2003b): Region 5 Ecological Screening Levels (Water)
- EPA (2006): EPA Region 3 BTAG Freshwater Benchmarks
- EPA (1995b): Region 4 Chronic Surface Water Screening Benchmarks
- EPA (2001b): Region 6 Surface Water Screening Benchmark
- Suter, G.W., II, and C.L. Tsao. (1996): Tier II Secondary Chronic Values (SCVs)
- EPA (2011): Great Lakes Initiative Toxicity Data Clearinghouse aquatic life, chronic concentrations

4.8.3 Pore Water

As discussed in detail in Section 4.5, sediment pore water concentrations are a better predictor of effects on benthic invertebrates than bulk sediment concentrations (Di Toro et al., 1991). When available, ESVs for pore water were selected from final chronic

values (FCVs) used in the derivation of equilibrium partitioning sediment benchmarks (ESBs) from the following sources:

- EPA (2008): *Procedure for the Derivation of Equilibrium Partitioning Sediment Benchmarks for the Protection of Benthic Organisms: Compendium of Tier 2 Values for Nonionic Organics*
- EPA (2003a): *Procedures for the Derivation of Equilibrium Partitioning Sediment Benchmarks for the Protection of Benthic Organisms: PAH Mixtures.*

In the absence of FCVs, pore water ESVs were conservatively selected from surface water benchmarks used to derive surface water ESVs, as described in Section 4.8.2. A summary of pore water ESVs used in the evaluation of pore water data is provided in Table 6.

5.0 Screening-Level Ecological Exposure Evaluation

This section describes the methodology used to conduct screening-level exposure estimates and risk calculations for selected receptor categories, consistent with Step 2 of ERAGS (EPA, 1997). This section describes the data used to conduct the SLERA, specifies the criteria for COPEC selection, and establishes the basis for exposure estimation and risk characterization.

5.1 Data Used to Characterize Ecological Exposure

The following subsections describe the datasets used in the screening-level evaluation of exposure in the Former Seep Area and the Canal-Wide Area.

5.1.1 Former Seep Area

As stated in Section 1.0, the purpose of the SLERA is to use relevant data to evaluate ecological exposure in the Salem Canal following the installation of the SPB in December 2008. Therefore, analytical data for bulk sediment, sediment pore water, and surface water collected within the Former Seep Area since 2009 were used in the screening-level exposure estimate. A summary of the number of environmental samples included the exposure evaluation is presented below; bulk sediment sample locations are depicted in Figure 4 and pore water sampling stations are depicted in Figure 5. A summary of analytical data is provided in Appendix B.

Descriptor	Bulk Sediment	Sediment Pore Water	Surface Water ^B
Number of Sample Stations ^A	60	30	22
Years Evaluated (Number of Stations)	2009 (3), 2011 (35), and 2015 (22)	2009 (8), 2013 (3), 2015 (5), 2016 (11), and 2018 (3)	2009 (3), 2011 (1), 2013 (14), and 2018 (3)

Notes:

- A. Certain sample locations were sampled multiple times and the number of samples varied by analytes.
 B. Surface water data from the Former Seep Area were combined with surface water data from the Canal-Wide Investigation to evaluate screening-level exposure.

Bulk Sediment

Direct contact ecological exposure to bulk sediment was conservatively evaluated at the 0 to 0.5-foot and 0.5- to 1.0-foot sampling intervals. As previously discussed in Section 4.5.1, benthic invertebrate receptors are exposed in the BAZ, which operationally extends from the SWI to a maximum depth of 0.5 feet below the SWI. In addition to evaluating sediment samples collected within the BAZ, sediment data from the sampling interval immediately below the BAZ (0.5 to 1.0 foot) were evaluated consistent with NJDEP *Ecological Evaluation Technical Guidance* (NJDEP, 2018). NJDEP (2018) recommends the evaluation of both sampling intervals to conservatively evaluate exposure at sites like the Salem Canal where groundwater-to-surface water discharge was a predominant transport pathway prior to the installation of the SPB (see Section 4.2). Four samples were collected within the 0 to 6-inch interval within the Former Seep Area: 0 to 0.08-foot (0 to 1 inch), 0.08- to 0.16-foot (1 to 2 inches), 0.16- to 0.33-foot (2 to 4 inches), and 0.33- to 0.5-foot (4 to 6 inches). These data were used to

estimate depth-weighted average concentrations for the 0 to 0.5-foot interval. Below the 0 to 0.5-foot interval, samples were collected in 0.5-foot intervals to the maximum depth of sediment. This sampling design meets or exceeds the guidance in Section 5.3.3.1 of the EE Technical Guidance regarding the vertical resolution of bulk sampling to support an ecological evaluation for subsurface or surface discharges.

Samples were analyzed for site-related priority pollutant (PP) SVOCs, including PAHs, and PP VOCs. Further details regarding the data collection and results are presented in URS (2013) and AECOM and EHS Support (2017). A summary of sediment analytical data used in the screening-level exposure evaluation is provided in Appendix B.

Pore Water

Pore water data were collected in the Former Seep Area to develop vertical profiles of seep-related constituents in pore water to monitor sediment recovery consistent with DuPont CRG (2007), including CSIA studies to assess the biodegradation of seep-related constituents. Pore water data collected within BAZ during these investigations are used in the SLERA to estimate C_{free} exposure concentrations for benthic invertebrates.

Sediment pore water samples were collected from stations within the Former Seep Area in 2009, 2013, 2015, 2016, and 2018. Samples in 2009 were collected via (1) centrifuged pore water from bulk sediment samples and (2) pore water peepers. Samples in 2013, 2015, 2016, and 2018 were collected using a modified peeper design that enabled the collection of greater sample volume (see Appendix F in URS, 2013). The comparability of pore water data results from 2009 may be somewhat limited due to differences in sampling methods; however, all available pore water data collected following the installation of the SPB were included in the SLERA for completeness.

Sediment pore water samples were collected from multiple sampling intervals during the various sampling events to provide vertical concentration profiles of seep-related constituents. Pore water exposure is evaluated in the SLERA using samples relevant to benthic invertebrate exposure in surficial sediment sampling intervals. Pore water data from three intervals within the top 1-foot of sediment are used to evaluate exposure based on the data available for each interval:

- 0 to 0.5-foot
- 0.5 to 0.75-foot
- 0.75 to 1.0-foot

The 0 to 0.5-foot interval represents exposure within the BAZ, where the greatest interactions between benthic receptors and pore water is expected to occur. The 0.5 to 0.75-foot and 0.75 to 1.0-foot intervals conservatively evaluate exposure in the sampling interval immediately below the BAZ. These pore water sampling intervals are consistent with NJDEP (2018) for sediment in the 0-0.5-foot interval and provided greater resolution than NJDEP (2018) requires for the 0.5-1-foot exposure interval.

A summary of pore water analytical data used in the screening-level exposure evaluation is provided in Appendix B.

Surface Water

Surface water samples from the Former Seep Area were collected from 22 sampling stations. Near-bottom surface water samples (approximately 0.5-foot above the SWI) were collected in 2009 (May, June, July and August), 2011 (August), 2013 (October),

and 2018 (November). Samples were analyzed for PP VOCs and PP SVOCs. As stated in Section 4.7, surface water data from the Former Seep Area are combined with surface water data from the Canal-Wide Area to provide a holistic, canal-wide evaluation of complete exposure pathways to COPECs in surface water within the Salem Canal. A summary of surface water analytical data used in the screening-level exposure evaluation is provided in Appendix B.

5.1.2 Canal-Wide Area

Sediment and surface water data to support the evaluation of ecological exposure in the Canal-Wide Area were collected in Reach 1, Reach 2, Tidal Reach, and an upstream Reference Reach in August 2016. Samples were collected in accordance with the *Salem Canal Characterization Sampling Plan* (AECOM, 2016a) and the results were reported in the *2017 Salem Canal Investigation Summary Report* (AECOM and EHS Support, 2017). The overall study design was based on a grid sampling design to enable a systematic characterization of sediment and surface water quality in the Salem Canal adjacent to the site (AECOM, 2016). Within the grid design, targeted outfall samples were collected from stations adjacent to historical or active outfalls to characterize point source inputs and transect samples were collected at stations spaced throughout the study area to characterize potential point and non-point source inputs. A summary of the number of bulk sediment and surface water sampling stations for each reach is provided below:

Reach	Bulk Sediment	Surface Water
Reach 1 (see Figure 6)	21	3
Reach 2 (see Figure 7)	28	3
Tidal Reach (see Figure 8)	20	3
Reference Reach (see Figure 9)	9	3

The following subsections describe the bulk sediment and surface water data included in the screening-level exposure evaluation of the Canal-Wide Area.

Bulk Sediment

Within the Canal-Wide Area, sediment samples were collected from the 0 to 0.5-foot and 0.5- to 1-foot intervals and select intervals below the 0 to 1-foot sampling interval. Sediment data from the 0 to 0.5-foot and 0.5 to 1.0-foot sampling intervals are included in the screening-level exposure evaluation, consistent with NJDEP (2018). The analytical scope for sediment included analyses of target analyte list (TAL) metals, target compound list (TCL) VOCs, TCL SVOCs, PCBs, pesticides, and perfluorinated compounds; analytical methods performed were consistent with the sampling plan (AECOM, 2016a). TCL VOCs and SVOCs analyses were only conducted on samples from three locations within Reach 2 due to the extensive characterization of VOCs and SVOCs in the Former Seep Area (AECOM and EHS Support, 2017). A summary of sediment analytical data used in the screening-level exposure evaluation is provided in Appendix B.

Sediment data for perfluorinated compounds were not included in the ecological exposure evaluations presented in the SLERA. Further discussion of the distribution of perfluorinated compounds in sediment within the Salem Canal is presented in AECOM

and EHS Support (2017). Analyses of poly- and perfluoroalkyl substances in bulk sediment samples collected from the Salem Canal were incorporated into the multimedia evaluation presented in the *Conceptual Site Model (CSM) for Poly- and Perfluoroalkyl Substances (PFAS)* developed to identify sources of PFAS and potential migration pathways that may have resulted in detections of PFAS in off-site media (AECOM, 2017).

Surface Water

Near-bottom surface water samples (approximately 0.5-foot above the SWI) were collected at 12 stations, as indicated above and illustrated in Figures 6 through 9. Samples were collected using a Kemmerer bottle sampler or a peristaltic pump with dedicated tubing. The analytical scope for surface water included analyses of TAL metals, TCL VOCs, TCL SVOCs, PCBs, pesticides and perfluorinated compounds, performed by the methods outlined in the Canal-Wide SAP (AECOM, 2016a). Surface water analysis for metals was conducted on field-filtered [0.45-micrometer (μm) filter] and unfiltered samples. Total hardness (as CaCO_3) was measured in unfiltered surface water samples for the calculation of hardness-dependent surface water quality criteria. A summary of surface water analytical data used in the screening-level exposure evaluation is provided in Appendix B.

Surface water data for perfluorinated compounds were not included in the ecological exposure evaluations presented in the SLERA. Further discussion of the distribution of perfluorinated compounds in surface water within the Salem Canal is presented in AECOM and EHS Support (2017). Analyses of poly- and perfluoroalkyl substances in surface water samples collected from the Salem Canal were incorporated into the multimedia evaluation presented in the *Conceptual Site Model (CSM) for Poly- and Perfluoroalkyl Substances (PFAS)* developed to identify sources of PFAS and potential migration pathways that may have resulted in detections of PFAS in off-site media (AECOM, 2017).

In addition to chemical analyses, *in situ* measurements of near bottom surface water parameters were recorded at each surface water sampling location. Surface water parameters, including temperature, pH, dissolved oxygen, specific conductivity, and oxidation-reduction potential (ORP) were measured with a YSI 556 multi-parameter water quality meter (YSI Incorporated).

5.1.3 Background Characterization

Background concentrations may be used in COPEC refinement step to effectively focus the ecological risk assessment (EPA, 2001c). The use of background datasets is also incorporated into NJDEP Ecological Evaluation Technical Guidance to refine the COPEC list, to assess whether COPECs may be site-related, and to evaluate site COPEC concentrations relative to regional COPEC concentrations (NJDEP, 2018).

Sediment and surface water data collected from the Reference Reach located upstream of the Canal-Wide Area were used to characterize non-site related anthropogenic constituent contributions from up-gradient of the site, including transportation infrastructure (see Figure 2). Sediment and surface water data from Reach 1 and Reach 2 were compared to sediment and surface water data collected in the upstream Reference Reach. Background threshold values (BTVs) were calculated from background datasets using EPA ProUCL 5.1 to provide representative background concentrations for Reach 1 and Reach 2.

Due to the connectivity of the Tidal Reach to the Delaware River below Munson Dam, sediment data from the Tidal Reach were compared to regional sediment data, consistent with the approach used in the *Delaware River Screening-Level Ecological Risk Assessment* (EHS Support, 2018). Regional sediment data obtained from the National Oceanic and Atmospheric Administration (NOAA) Data Integration Visualization Exploration and Reporting (DIVER) database were used to estimate representative background concentrations for comparisons with sediment concentrations measured within the Tidal Reach. Available data for Zone 5 of the Delaware River were downloaded from the DIVER database on September 21, 2018 and imported into ArcGIS (ESRI). Surficial sediment samples (0 to 2-3 centimeters) collected after 2000 were the focus of the evaluation based on the availability of surficial data in DIVER. Sediment samples collected within the section of Zone 5 adjacent to Chambers Works, from the Delaware Memorial Bridge north to Carneys Point, were excluded from the background assessment to minimize the potential influence of the site on the estimation of representative background concentrations. Constituents of interest in the sediment background assessment included: select metals, PCBs, and PAHs. Metals data from the Delaware Benthic Inventory (DEBI) Project 2008 were not retained in the evaluation due to the use of an inconsistent chemical extraction procedure.

95th percentile upper prediction limits (UPLs), upper threshold limits (UTLs), and upper simultaneous limits (USLs) of the distribution were calculated for each compound. Consistent with the Delaware River SLERA, the UPL was adopted as the BTV for all constituents except iron, which used the more conservative UTL value.

5.1.4 Data Usability

The AECOM Analytical Data Quality Management (ADQM) Group conducted data validation on electronic data deliverables using the data verification model (DVM) process. This process reviews and evaluates laboratory data including hold time criteria, blank contamination, matrix spike/matrix spike duplicate (MS/MSD) recoveries, duplicate sample relative percent difference (RPD), and surrogate recoveries. Based on the DVM process, the following qualifiers were assigned to the sediment and surface water data as applicable:

Qualifier	Definition
R	Unusable result. Analyte may or may not be present in the sample.
J	Analyte present. Reported value may not be accurate or precise.
UJ	Not detected. Reporting limit may not be accurate or precise.

As provided in Appendix C, the results of the DVM data review indicate that the samples were considered useable in consideration of the objectives for the investigation and no significant quality control exceptions were noted. ADQM data review narratives are provided in Appendix C. Complete analytical data packages have been submitted in previous reports (URS, 2013; AECOM and EHS Support, 2017). NJDEP HazSite deliverables for data used the SLERA have also been submitted with previous reports.

5.2 Exposure Estimate Methodology

The following subsections describe the methodologies used to conduct the screening-level exposure evaluation based on the available data described in the previous section.

5.2.1 Direct Contact Screening Evaluation

The preliminary screening-level exposure evaluation involved comparing maximum concentrations observed in bulk sediment, sediment pore water, and surface water with the previously described medium-specific ESVs (see Section 4.8). The preliminary exposure estimate presents the most conservative exposure scenario based on the most conservative exposure assumptions. Preliminary exposure assumptions based on comparison to maximum EPCs for each exposure area are presented below for each receptor category:

- **Benthic Invertebrate Community:** Comparisons of maximum COPEC concentrations measured in bulk sediment and sediment pore water to conservative ESVs.
- **Fish Community:** Comparisons of maximum COPEC concentrations in surface water to conservative ESVs.

5.2.2 Wildlife Ingestion Pathway Evaluation

Wildlife ingestion exposure pathways were evaluated for exposure to constituents with the potential to bioaccumulate. Bioaccumulative constituents were defined as organic constituents with log K_{ow} values greater than 3.5 (see Section 4.5.1) and inorganic constituents identified by EPA as important bioaccumulative constituents (EPA, 2000).

Deterministic dose rate models were developed to estimate the daily dose (EDD) that semi-aquatic wildlife receptors may receive through foraging activities in the Salem Canal. Wildlife receptors that may be present in the Salem Canal would likely forage over a broad area, therefore, the deterministic models incorporated exposure data collected within the Former Seep Area and the Canal-Wide Area to provide a holistic estimation of the EDD within the Salem Canal.

For the screening-level evaluation, deterministic models were based on the most conservative EPCs to represent EDDs based on the reasonable maximum exposure (RME) that wildlife receptor may receive assuming typical exposure factors.

EDDs were compared to conservative toxicity reference values (TRVs) based on survival, growth, or reproduction endpoints. Two tiers of chronic TRVs representing no observed adverse effects levels (TRV_{NOAEL}) and lowest observed adverse effect levels (TRV_{LOAEL}) were identified. Only TRV_{NOAEL} values were used in the screening-level exposure evaluation. If the conservative estimates of exposures are below TRVs that are not known to cause adverse effects, then the potential for adverse effects is not likely. If the EDD exceeds the TRV_{NOAEL} based on the RME, the deterministic model is refined to reflect more representative exposure scenarios (Section 7.2).

Overview of Dietary Exposure Models

The following equation forms the basis for the point exposure estimate for a given receptor:

$$EDD_{total} = \frac{IR_{diet} \times \sum (BSAF_{dw} \times C_{substrate} \times DF_i) \times AUF}{BW} + \frac{IR_{substrate} \times C_{substrate} \times AUF}{BW}$$

where:

EDD_{total} = Estimated daily dose (mg COPEC/kg BW/day)

BW = Body weight (kg)

IR_{diet} = Ingestion rate of food [kg food/day, dry weight (dw)]

$BSAF_{dw}$ = Biota-sediment accumulation factor (BSAF), specific to prey type and COPEC (kg sediment/kg tissue, dw)

$C_{sediment}$ = COPEC concentration in sediment (mg COPEC/kg, dw)

DF_i = Dietary fraction of item i in total diet (proportion)

$IR_{sediment}$ = Incidental ingestion rate of sediment (kg/day, dw)

AUF = Area use factor for exposure area; an AUF of 1.0 is assumed

General discussion of parameter estimation is provided below; additional details regarding the parameterization of the deterministic models are provided in Appendix D.

Exposure Parameter Estimation

The deterministic model was used in the screening-level evaluation to estimate a RME for a typical representative receptor. Therefore, average and/or typical values of exposure factors were used (e.g., mean BW and typical dietary preference). Various literature sources were reviewed to select the receptor-specific exposure factors, including the Wildlife Exposure Factors Handbook (EPA, 1993b). An area use factor (AUF) of 1 was assumed in the screening-level evaluation. Receptor-specific values for exposure factors used in the deterministic models are presented in Appendix D.

Estimation of Exposure Point Concentrations

For the screening-level exposure evaluation, EPCs were estimated in the deterministic models based on maximum COPEC concentrations in sediment samples collected within the BAZ (0 to 0.5-foot sampling interval) in the Former Seep Area and Canal-Wide Area. COPEC concentrations in dietary items were estimated based on biota-sediment accumulation factors (BSAFs) obtained from literature sources (e.g., DiToro and McGrath, 2000, Bechtel, 1998) or the U.S. Army Corps of Engineers BSAF Database (USACE, 2017). Further detail regarding the estimation of EPCs is provide in Appendix D.

Toxicity Reference Values

The EDD is compared to conservative TRV_{NOAEL} values to evaluate the potential for adverse effects to wildlife receptors. Consistent with NJDEP (2018), the selection of TRVs to evaluate the potential for adverse effects to wildlife receptors was based on a tiered approach. In the screening-level evaluation, TRVs were selected from first tier TRV sources identified by NJDEP (Table 1 in NJDEP, 2018). In the absence of TRVs from NJDEP (2018), alternate TRVs were primarily obtained from second tier sources including compilations of toxicity data for EPA Ecological Soil Screening Levels (Eco-SSLs; EPA (2005c)) and other sources including EPA (2007b) and Sample et al. (1996). For constituents with EDDs exceeding first tier TRVs in the screening-level exposure evaluation, alternative TRVs were considered in the refined exposure evaluation (Section 7.3.3). Appendix D contains a summary of selected TRVs and associated sources.

5.2.3 Fish Ingestion Pathway Evaluation

The ECSM includes potentially complete pathways for demersal fish, including the direct ingestion of sediment-associated biota and direct contact with bulk sediment and pore water. However, the revised ECSM distinguishes between primary pathways that are

quantitatively evaluated and secondary pathways that may be complete, but are not quantitatively evaluated.

To address EPA comments on the April 2017 Revised SLERA regarding potential dietary exposure to demersal fish, a literature review was conducted to identify toxicological endpoints to support a quantitative assessment of dietary ingestion pathways to fish. The EPA ECOTOXicology Database (ECOTOX) was queried for survival, growth, or reproductive endpoints for fish based on dietary exposure to bioaccumulative COPECs. Consistent with the wildlife ingestion pathway evaluation (see Section 5.2.2), bioaccumulative constituents were defined as detected organic constituents with log K_{ow} values greater than 3.5 and detected inorganic constituents identified by EPA as important bioaccumulative constituents (EPA, 2000). Selected studies were based on juvenile and adult life stages that would potentially forage on benthic invertebrates in sediment within the Salem Canal. Geometric mean concentrations for NOEC and LOEC endpoints for survival, growth, or reproductive endpoints were calculated for comparison with estimated concentrations in dietary items in the Salem Canal. A summary of the selected ECOTOX studies is presented in Appendix D.

Estimated dietary concentrations in sediment-associated prey in the Salem Canal were directly compared to geometric mean dietary endpoints calculated from ECOTOX studies. For screening-level exposure evaluations, maximum concentrations estimated in benthic invertebrate prey items (see Section 5.2.2; Appendix D) were compared to dietary NOEC and LOEC endpoints for survival, growth, and reproduction in fish.

5.3 Risk Characterization

Potential risks associated with screening-level ecological exposure estimates were expressed as hazard quotient (HQs), which represent the ratio of the EPC to the ESV for direct contact pathways:

$$HQ = \frac{EPC}{ESV}$$

Potential direct contact risk may be characterized based on HQs, as follows:

- HQs less than 1.0 indicate limited potential for adverse effects because COPEC concentrations result in an exposure that has not been demonstrated to cause adverse ecological effects.
- HQs greater than 1.0 indicate that an EPC for the COPEC exceeds an ecological benchmark representing a NOEC. Therefore, the potential for adverse effects cannot be dismissed; further evaluation of direct contact exposure may be warranted.

Potential risks associated with dietary exposure to wildlife were expressed as hazard quotient (HQs), which represents the ratio of the EDD to TRV:

$$HQ = \frac{EDD}{TRV}$$

HQs are calculated for NOAEL-based TRVs (HQ_{NOAEL}) and LOAEL-based TRVs (HQ_{LOAEL}) for each EDD. Potential risk may be characterized based on HQs, as follows:

- HQ_{NOAEL} less than 1.0 indicates limited potential for adverse effects because the estimated EDD is below the minimum NOAEL TRV identified in the literature; the potential for adverse effects is negligible.
- HQ_{NOAEL} greater than 1.0 and HQ_{High} less than 1.0 indicate that the EDD exceeds a conservative NOAEL TRV, but is within the range of NOAEL TRVs identified in the literature; the potential for adverse population-level effects is minimal.
- HQ_{LOAEL} greater than 1.0 indicates that the EDD exceeds a NOAEL TRV and the potential for adverse effects cannot be dismissed; further evaluation of dietary exposure may be warranted.

5.4 COPEC Selection

The results of the COPEC screening for each environmental medium include the following:

- Number of samples
- Frequency of detection
- Maximum EPC
- Location and year of maximum EPC
- ESV
- Hazard Quotient (HQ)

Constituents were retained as COPECs when:

- Maximum EPC was above the ESV ($HQ > 1$) and the laboratory MDL.
- No ESV was available.

The exclusion of constituents with MDLs above the ecological screening level is a source of uncertainty in the exposure assessment that is discussed further in the uncertainty evaluation presented in Section 9.0.

BTVs calculated from the upstream Reference Reach and regional sediment data collected in Zone 5 of the Delaware River (see Section 5.1.3) are presented in the screening-level exposure evaluation to provide regional context for data from site reaches. Sediment COPECs were not excluded in the screening-level exposure estimate based on comparisons to BTVs. Further consideration of BTVs is included to refine the list of sediment COPECs as part of the refined ecological exposure evaluation (see Section 7.2.4). Surface water data from the upstream Reference Reach were considered for iron and aluminum in the selection of surface water COPECs (see Section 6.1.1).

5.5 Scientific Management Decision Point

The SMDP is a determination made at the completion of Step 2 of the SLERA process that states whether there is sufficient information to support risk management decision-

making (EPA, 1997). The preliminary risk calculation will be used to support one of the following decision points regarding the need for further risk evaluation:

- There is adequate information to conclude that ecological risks are negligible; therefore, there is no need for remediation on the basis of ecological risk.
- The information is not adequate to make a decision at this point, and the ecological risk assessment process will continue to Step 3.
- The information indicates a potential for adverse ecological effects, and a more thorough assessment is warranted.

6.0 Screening-Level Exposure Estimate and Risk Characterization

This section presents the results of the screening-level exposure estimates and risk characterizations for the Former Seep Area and the Canal-Wide Area investigated in the Salem Canal.

6.1 Former Seep Area

The following subsections identify COPECs and present the screening-level exposure estimates for the benthic community that may be exposed to COPECs in sediment and pore water in the Former Seep Area.

6.1.1 COPEC Identification

The results of the preliminary comparisons of maximum EPCs to conservative ESVs were used to identify COPECs for further evaluation in the Former Seep Area. The results of the screening-level evaluation are presented in the following tables for relevant exposure media: bulk sediment (see Tables 7 and 8) and sediment pore water (see Tables 9 through 11).

Based on maximum concentrations of constituents exceeding conservative ESVs, the following COPECs were identified for bulk sediment and sediment pore water.

Constituent	Bulk Sediment		Pore Water	
	Sample depth (feet): 0 - 0.5	0.5 - 1.0	0 - 0.5	0.5 - 1.0
Volatile Organic Compounds				
Acetone	●	●		
Benzene	●	●		
Carbon disulfide	●	●		
Chlorobenzene	●	●	●	●
Cumene	●			
Methyl ethyl ketone	●			
Total xylenes	●	●		
Semi-Volatile Organic Compounds				
Aniline	●	●		●
Bis(2-ethylhexyl)phthalate	●		●	●
2-Chlorophenol	●	●		●
4-Chloroaniline	●	●		
1,2-Dichlorobenzene	●	●		
1,3-Dichlorobenzene	●			
1,4-Dichlorobenzene	●	●		
Hexachlorobenzene	●			
2-Methylnaphthalene	●	●		
2-Methylphenol			●	
N-Nitrosodiphenylamine	●	●		
Phenol	●	●		
Polycyclic Aromatic Hydrocarbons				
Total PAHs	●	●		

In addition to the constituents identified above, 11 additional VOCs and six additional SVOCs were identified as COPECs because an ESV was not identified from the sources listed in Section 4.8. Constituents identified as COPECs due to the lack of conservative ESVs are listed for bulk sediment in Tables 7 and 8 and pore water in Tables 9 through 11. Potential exposure to these constituents will be addressed as an uncertainty in the SLERA (see Section 9.1.1). Further evaluation of benthic invertebrate exposure to COPECs with maximum EPCs exceeding conservative ESVs is presented in the following subsection.

6.1.2 Screening-Level Exposure Estimate

This section presents the results of the screening-level exposure estimate for benthic invertebrates in Former Seep Area of the Salem Canal. Based on the measurement endpoints identified in Section 4.7, exposure of benthic invertebrate receptors was evaluated based on comparisons of COPEC concentrations in bulk sediment and sediment pore water. The following subsections summarize screening-level exposure estimates based on comparisons of maximum concentrations of bulk sediment and pore water to conservative ESVs.

Bulk Sediment

Screening-level estimates of benthic invertebrate exposure to bulk sediment in the BAZ (0 to 0.5 feet) are summarized in Table 7. Chlorobenzene, carbon disulfide, acetone, dichlorobenzenes, and benzene had the highest HQs based on maximum exposure concentrations and conservative ESVs. HQs for other VOCs with maximum concentrations exceeding ESVs were less than 2 (see Table 7). Chlorobenzene had the greatest detection frequency (97 percent) in samples collected from the 0 to 0.5-foot sampling interval, followed by carbon disulfide and acetone. Of the 10 SVOCs with maximum concentrations exceeding ESVs, aniline had the greatest HQs (see Table 7). Fifteen of 16 individual PAHs had maximum concentrations exceeding ESVs; the maximum total PAH concentration also exceeded the conservative ESV.

In the interval below the BAZ, maximum concentrations of seven VOCs and eight SVOCs plus PAHs exceeded conservative ESVs (see Table 8). Similar to the surficial interval (0 to 0.5 feet), chlorobenzene, benzene, acetone, dichlorobenzenes, and carbon disulfide had the highest HQs; aniline had the greatest HQ for the non-PAH semi-volatile COPECs. Maximum concentrations of 13 of 16 individual PAHs exceeded ESVs and maximum total PAH concentrations exceed the ESV, resulting in HQs of 2.1 and 2.2 (see Table 8).

A kriging analysis of the spatial distribution of primary COPECs within the BAZ and the 0.5-1-foot sampling interval in the Former Seep Area was presented in the *2017 Salem Canal Investigation Summary Report* (AECOM and EHS Support, 2017). Figure 10 illustrates the estimated average concentration of chlorobenzene, and Figure 11 illustrates the estimated average concentration of dichlorobenzenes, calculated as the summed concentrations of 1,2-dichlorobenzene, 1,3-dichlorobenzene, and 1,4-dichlorobenzene. The analysis indicates that the concentrations of these primary COPECs are generally greater in the nearshore area in the vicinity of station SCD-151. Estimated average concentrations of chlorobenzene and dichlorobenzene are generally lower in the BAZ than the 0.5-1-foot interval immediately below the BAZ (see Figures 10 and 11).

Pore Water

The preliminary estimate of pore water exposure indicates that relative to bulk sediment, maximum concentrations of fewer constituents exceeded ESVs and the magnitude of exceedances was substantially lower (see Tables 9 to 11). Based on the maximum EPC, the HQ for chlorobenzene in pore water samples collected within the BAZ was 4.3 (see Table 9). Bis(2-ethylhexyl)phthalate was the only SVOC detected in pore water samples collected within the BAZ with a maximum concentration exceeding an ESV (HQ=11.3). Naphthalene was the only PAH detected in pore water samples collected within the BAZ; however, naphthalene was detected in less than 25 percent of samples and the maximum concentration was substantially lower than the ESV.

Overall, maximum concentrations of pore water COPECs were greater in samples collected within the 0.5-1.0-foot sediment interval relative to the 0 to 0.5-foot interval. Chlorobenzene was the only volatile COPEC detected in pore water samples within the 0.5-0.75-foot and 0.75-1-foot sediment intervals at maximum concentrations greater than ESVs. Resulting chlorobenzene HQs for the 0.5-0.75-foot and 0.75-1-foot intervals were 5.5 and 5.7, respectively (see Tables 10 and 11). Bis(2-ethylhexyl)phthalate, aniline, and 2-chlorophenol were the only SVOCs with maximum concentrations exceeding ESVs in pore water samples below the BAZ. Like the surface interval, no individual PAHs were detected at concentrations exceeding ESVs in pore water samples collected from 0.5 to 1.0-foot (see Tables 10 and 11).

6.1.3 Screening-Level Risk Characterization and SMDP

The screening-level exposure estimates presented in the previous section represent the most conservative exposure scenarios based on the comparisons of maximum COPEC concentrations to conservative ESVs. A preliminary characterization of potential risks is presented based on these conservative exposure assumptions to identify COPECs and exposure pathways that may warrant further evaluation. This preliminary characterization of potential risks is summarized below by receptor category:

- **Benthic Invertebrate Community:** A conservative evaluation of measurement endpoints for benthic invertebrates indicates the potential for adverse ecological effects resulting from exposure to COPECs in bulk sediment within the Former Seep Area. Maximum concentrations of several VOCs, SVOCs, and total PAHs in bulk sediment exceeded conservative ESVs. Comparisons of maximum pore water concentrations to ESVs indicate less potential for adverse effects when compared to the bulk sediment evaluation. However, maximum concentrations of chlorobenzene, aniline, bis(2-ethylhexyl)phthalate, and 2-chlorophenol in pore water samples collected within the BAZ exceeded conservative ESVs.

Based on the screening-level exposure evaluation, a refined direct contact evaluation for bulk sediment and sediment pore water is warranted as part of ERAGS Section 3.2 to further evaluate potential effects to benthic invertebrates associated with exposure to COPECs associated with the Former Seep Area. Exposure estimates for bulk sediment and pore water will be refined using more representative EPCs and more representative ESVs (see Section 8.0).

The risk characterization presented above supports the following SMDP for exposure to seep-related constituents in the Salem Canal:

- The information indicates a potential for adverse ecological effects, and a more thorough assessment is warranted.

Further evaluation of the direct contact exposure pathways to benthic invertebrates is conducted in ERAGS Section 3.2, as presented in Section 8.0.

6.2 Canal-Wide

This section identifies COPECs and present the screening-level exposure estimates for the ecological receptors that may be exposed to COPECs in surface water and sediment in the Canal-Wide Area. As discussed in the preliminary problem formulation (see Section 4), the assessment for the Canal-Wide Area includes screening-level exposure evaluations for the following receptor groups:

- Benthic invertebrate community
- Fish – including exposure within the Former Seep Area
- Semi-aquatic wildlife – including exposure within the Former Seep Area.

6.2.1 COPEC Identification

The results of the preliminary comparisons of maximum EPCs to conservative ESVs were used to identify sediment and surface water COPECs for further evaluation in Reach 1, Reach 2, and the Tidal Reach. To provide regional context to the identification of COPECs in site reaches, sampling results for the Reference Reach are summarized in Table 12 (0-0.5-foot) and Table 13 (0.5-1-foot) for bulk sediment. A summary of selected BTVs and associated summary statistics using data from the DIVER database are presented in Table 14 (see Section 5.1.3). Table 15 summarizes surface water sampling results for the Reference Reach. Concentrations in Reference Reach samples that exceed conservative ESVs are presented in Figures 12 and 13 for sediment and surface water, respectively.

Bulk Sediment

The results of the screening-level evaluation for site reaches are presented in the following tables for bulk sediment:

- Reach 1: Tables 16 (0-0.5-foot) and 17 (0.5-1-foot)
- Reach 2: Tables 18 (0-0.5-foot) and 19 (0.5-1-foot)
- Tidal Reach: Tables 20 (0-0.5-foot) and 21 (0.5-1-foot)

Based on maximum concentrations of constituents exceeding conservative ESVs, the following COPECs were identified for bulk sediment in the following site reaches:

Constituent	Reach 1		Reach 2		Tidal Reach	
	0-0.5	0.5-1.0	0-0.5	0.5-1.0	0-0.5	0.5-1.0

Notes:

NA, Analyte was not analyzed in depth interval.

In addition to the constituents identified above, additional VOCs, SVOCs, pesticides, and metals were identified as COPECs because an ESV was not identified from the sources listed in Section 4.8. Constituents identified as COPECs due to the lack of conservative

ESVs are listed for bulk sediment in Tables 16 through 21. Potential exposure to these constituents will be addressed as an uncertainty in the SLERA (see Section 9.1.1).

Surface Water

The results of the screening-level evaluation for surface water are presented in Table 22 (Reach 1), Table 23 (Reach 2), and Table 24 (Tidal Reach). Detected constituents in surface water are illustrated in Figure 14 (Reach 1), Figure 15 (Reach 2), and Figure 16 (Tidal Reach).

The screening-level evaluation did not identify site-related COPECs in any surface water samples collected within the Salem Canal. Aluminum and iron in unfiltered samples were the only constituents with maximum concentrations exceeding conservative ESVs. However, concentrations of these metals also exceeded ESVs in the Reference Reach upstream of Chambers Works (see Table 15 and Figure 13). Overall, concentrations of dissolved TAL metals were generally consistent between the upstream Reference Reach and Reaches 1 and 2 adjacent to Chambers Works. These results indicate that surface water quality related to metals is consistent with regional surface water quality conditions; therefore, aluminum and iron are not identified as surface water COPECs in the SLERA.

No organic constituents were detected in surface water samples at concentrations exceeding conservative ESVs. Chlorobenzene, the primary COPEC associated with the Former Seep Area, was detected in two of 25 samples collected within Reach 2 between 2009 and 2018 (Table 23) and in one sample in the Tidal Reach in 2016 (Table 24). However, the detected concentrations of chlorobenzene were only slightly above the analytical detection limit and substantially below the conservative ESV (see Tables 23 and 24). Limited detections of other organic constituents including pesticides, VOCs, SVOCs, and total PCBs were observed in the Canal-Wide Area; however, no constituents were detected at concentrations exceeding conservative ESVs.

Based on the screening-level exposure evaluation that assumes maximum exposure conditions, no COPECs were identified in surface water. These results are consistent with the findings of previous evaluations of potential surface water quality impacts in the Salem Canal (URS, 2013).

6.2.2 Screening-Level Exposure Estimate

The following subsections present the results of the screening-level exposure estimate for the Canal-Wide Area. The screening-level estimate evaluated exposure to benthic invertebrates in sediment within Reach 1, Reach 2 (outside of the Former Seep Area), and the Tidal Reach. Screening-level exposure estimates for fish and semi-aquatic wildlife include evaluation of the combined datasets for the Canal-Wide Area and Former Seep Area.

Benthic Invertebrates

Based on the measurement endpoints identified in Section 4.7, benthic invertebrate receptor exposure was evaluated based on comparisons of COPEC concentrations in bulk sediment. The following subsections summarize preliminary exposure estimates for benthic invertebrates by site reaches.

Reach 1

Preliminary estimates of benthic invertebrates to COPECs in bulk sediment in the BAZ (0 to 0.5 feet) and the 0.5-1-foot interval within Reach 1 are summarized in Tables 16

and 17, respectively. Figure 17 illustrates the location of samples with concentrations exceeding ESVs within Reach 1.

Maximum concentrations of SVOCs including PAHs, pesticides, total PCBs, and metals exceeded conservative ESVs in samples collected from the BAZ in Reach 1. Based on maximum concentrations of SVOCs, 2-methylnaphthalene, bis(2-ethylhexyl)phthalate, 13 of 16 individual PAH compounds, and total PAHs exceeded ESVs. The greatest HQs calculated were for acenaphthene, acenaphthylene, and bis(2-ethylhexyl)phthalate. However, the maximum concentration of total PAHs only slightly exceeded the ESV (HQ=1.6) and bis(2-ethylhexyl)phthalate was detected in only one of 18 samples (see Table 16). Pesticides were generally detected at low concentrations relative to ESVs with HQ values based on maximum detected concentrations ranging from 1.1 to 3 for the five pesticides with maximum concentrations exceeding ESVs. Dichlorodiphenyl-dichloroethane (DDD), dichlorodiphenyldichloroethene (DDE), and beta-hexachlorocyclohexane (beta-BHC) were detected in one of four samples in Reach 1. The maximum concentration of total PCBs slightly exceeded the ESV (HQ=1.5). Maximum concentrations of 12 metals exceeded ESVs; however, maximum concentrations of seven of 12 metals were below the BTV. The greatest HQ calculated for metals was lead (HQ=10.1); HQs for all other metals were less than 4 based on maximum concentrations in Reach 1 (see Table 16).

An evaluation of the spatial distribution of COPEC exceedances within the BAZ in Reach 1 indicates that maximum concentrations were generally observed at stations adjacent to outfall locations. Maximum benthic invertebrate exposure concentrations for COPECs with the greatest HQs were located in the BAZ at stations adjacent to outfalls (see Figure 17): lead [SC-213-OutV-(0-0.5)], bis(2-ethylhexyl)phthalate [SC-217-OutX-(0-0.5)], mercury [SC-204-OutQ-(0-0.5)], and zinc [SC-203C-OutP-(0-0.5)]. Stations across transects away from outfall locations had relatively few exceedances of ESVs based on the screening-level evaluation. This finding indicates that benthic invertebrate exposure to concentrations greater than ESVs is spatially-limited to localized areas adjacent to outfalls.

COPEC concentrations were generally greater in the 0.5-1-foot interval below the BAZ. For VOCs, acetone was detected at the greatest concentration relative to its ESV (HQ=28.3); maximum concentrations of carbon disulfide and methyl ethyl ketone were slightly greater than ESVs (HQs 1.3, and 1.1, respectively). 2-Methylnaphthalene and carbazole were SVOCs other than PAHs with maximum concentrations exceeding ESVs (HQs=7.9 and 1.1, respectively). Maximum concentrations of 16 individual PAHs evaluated as total PAHs exceeded ESVs, except for benzo(a)fluoranthene; total PAHs exceeded the ESV in two of 16 samples, with an HQ of 2.6 (see Table 17). Total PCBs slightly exceeded the conservative ESV, with a maximum HQ of 1.6. Maximum concentrations of 12 metals exceeded conservative ESVs. The greatest HQ for metals was observed for lead (HQ=44.8) and mercury (HQ=19.3); HQs for all other metals were less than 6 based on maximum concentrations (see Table 17).

Reach 2 (Outside of the Former Seep Area)

The results of the screening-level exposure estimate for benthic invertebrates in Reach 2 outside of the Former Seep Area are summarized in Tables 18 and 19 for the BAZ and 0.5-1-foot interval, respectively. Figure 18 illustrates the location of samples with concentrations exceeding ESVs.

Exceedances of ESVs were observed in the BAZ for SVOCs including PAHs, pesticides, and metals (see Table 18). For SVOCs not included in the evaluation of PAHs, biphenyl,

carbazole, and 2-methylnaphthalene were detected at maximum concentrations exceeding ESVs within the BAZ (maximum HQ = 10.5). Individual PAH compounds were detected at maximum concentrations greater than the ESV, with the exception of benzo(b)fluoranthene; however, total PAHs in only one of two samples exceeded the ESV for total PAHs (HQ=2.5). Maximum concentrations of three pesticides exceeded ESVs in the BAZ, with HQs ranging from 4 to 12.6 (see Table 18). Alpha chlordane was detected in one of three samples, but no ESV was identified to evaluate exposure to this constituent. Twelve metals had maximum concentrations greater than ESVs in samples collected in the BAZ; however, maximum concentrations of three of these metals were below BTVs. Maximum HQs for metals were calculated for lead and mercury with HQs of 13.5 and 13.9, respectively (see Table 18).

Maximum exposure to COPEC concentrations within the BAZ in Reach 2 was generally observed at stations adjacent to historical outfall locations. The greatest number of constituents exceeding ESVs and maximum concentrations of most COPECs were observed at two stations located adjacent to historical outfalls (see Figure 18): SC-187-OutC-(0-0.5) and SC-200-OutM-(0-0.5). Like Reach 1, stations across transects away from outfall locations had relatively few exceedances of ESVs based on the screening-level evaluation. This indicates that benthic invertebrate exposure to concentrations greater than ESVs is spatially-limited to localized areas adjacent to historical outfalls within Reach 2.

In samples collected within the 0.5-1-foot interval within Reach 2, maximum concentrations of VOCs, SVOCs including PAHs, pesticides, and metals were greater than ESVs (see Table 19). For VOCs and SVOCs, maximum HQs in the BAZ were observed for chlorobenzene, 1,4-dichlorobenzene, and 1,2-dichlorobenzene; HQs of other VOCs were generally less than 10 (see Table 19). 2-Methylnaphthalene, biphenyl, and carbazole were detected at maximum concentrations greater than respective ESVs, with maximum HQs ranging from 2.4 to 9.6. Maximum concentrations of individual PAH compounds were greater than ESVs, except for benzo(b)fluoranthene and fluorene; however, only one of two samples contained total PAHs greater than the ESV (HQ=3.0). Endosulfan I and beta-BHC concentrations were greater than ESVs with HQs of 10.7 and 5, respectively. Maximum concentrations of 12 metals exceeded ESVs in samples collected within the 0.5-1-foot interval in Reach 2; maximum HQs for metals were observed for cadmium (HQ=31.3), mercury (HQ=27.7), and zinc (HQ=19).

Tidal Reach

The results of the screening-level exposure estimate for benthic invertebrates in the Tidal Reach are summarized in Tables 20 and 21 for the BAZ and 0.5-1-foot interval, respectively. Figure 19 illustrates the location of samples with concentrations exceeding ESVs within the Tidal Reach.

In samples collected within the BAZ, SVOCs including PAHs, pesticides, and metals were detected at concentrations exceeding conservative ESVs (see Table 20). The maximum concentrations of 1,2-dichlorobenzene, 1,4-dichlorobenzene, 2-methylnaphthalene and 4-methylphenol resulted in HQs ranging from 2.8 to 6.9 based on maximum concentrations; other SVOCs detected in samples within the BAZ were below ESVs (see Table 21). Maximum concentrations of individual PAHs included in the calculation of total PAHs exceeded ESVs, except for benzo(b)fluoranthene; total PAH concentrations exceeded the ESV in three of 13 samples (maximum HQ=6.3). Four pesticides were detected at maximum concentrations exceeding ESVs, with HQs ranging from 1.4 (4,4'-DDE) to 5 (beta-BHC). Maximum concentrations of 13 metals

were greater than ESVs within the BAZ of the Tidal Reach; however, maximum concentrations of four of these 13 metals were below BTVs calculated based on regional data from the DIVER database (see Section 5.1.3). The greatest HQs for metals were observed for chromium (HQ=45) and lead (HQ=39); HQs for other metals with maximum concentrations exceeding ESVs were 6.5 or lower (see Table 20).

The spatial distribution of COPEC exceedances within the BAZ in the Tidal Reach varied by constituent. The greatest concentrations of chromium were observed in a mid-channel station (SC-237-TRT2M(0-0.5)) and stations near the southern shoreline of the Salem Canal (see Figure 19). The only exceedances of lead were observed in nearshore stations adjacent to outfalls SC-231-Out13(0-0.5) and SC-239-Out11(0-0.5). The maximum exposure to total PAHs within the BAZ was observed at SC-236-OutT2(0-0.5), located near historical Outfall 11. Similar to reaches upstream of Munson Dam, benthic invertebrate exposure to concentrations greater than ESVs is spatially-limited to localized areas; however, the location of these areas and potential sources are varied in the Tidal Reach.

In the 0.5-1-foot interval, maximum concentrations were greater than ESVs for VOCs, SVOCs including PAHs, pesticides, total PCBs, and metals (see Table 21). Of the 17 VOCs detected, acetone (HQ=49.5), 1,4-dichlorobenzene (HQ=10.4), 1,2-dichlorobenzene (HQ=8.2) and methyl ethyl ketone (HQ=1.6) had concentrations exceeding ESVs. Maximum concentrations were lower than ESVs for nine VOCs; ESVs were not identified for four detected VOCs (see Table 21). 2-Methylnaphthalene and 4-methylphenol were SVOCs not included in the evaluation of total PAHs to be detected at a concentrations greater than ESVs. Individual PAH compounds, except for benzo(b)fluoranthene were detected at concentrations exceeding ESVs; however, total PAH concentrations exceeded the ESV in only two of 13 samples (maximum HQ=3.7). 4,4'-DDE and total DDX (summed concentration of 4,4'-DDD, 4,4'-DDE, and 4,4'-DDT) slightly exceeded ESVs for pesticides (HQs of 2.0 and 1.6, respectively); maximum concentrations of other detected pesticides were below ESVs (see Table 21). Total PCBs exceeded the ESV in one of three samples (HQ=2.0). Maximum concentrations of 13 metals exceeded ESVs, with chromium having the greatest HQ (HQ=22). HQs for other metals with maximum concentrations greater than ESVs were below 6 (see Table 21).

Fish

Preliminary exposure estimates indicate that constituents detected in surface water pose negligible direct contact risk to fish. No COPECs were identified in surface water samples collected since 2009 (2009, 2011, 2013, 2016, and 2018). Aluminum and iron in unfiltered samples were the only constituents with maximum concentrations exceeding conservative ESVs. However, concentrations of these metals also exceeded ESVs in the Reference Reach (see Section 6.2.1). The only seep-related constituents detected in surface water include chlorobenzene and acetone, which were detected at concentrations below ESVs; concentrations of other organic constituents detected in surface water, including SVOCs, pesticides, and total PCBs, were also below ESVs. Based on these results, potential direct contact risks to fish exposed to site-related constituents in surface water are negligible.

Dietary exposure to fish was evaluated based on comparisons of estimated concentrations in benthic invertebrates (see Section 5.2.2) to dietary endpoints for fish survival, growth, and reproduction (see Section 5.2.3). Maximum estimated concentrations of cadmium, mercury, zinc, total DDX and total PCBs exceeded NOEC

benchmarks for dietary concentrations for fish that could be derived based on ECOTOX data (Table 25). Maximum estimated dietary concentrations of cadmium and total PCBs exceeded LOEC benchmarks for growth endpoints.

Semi-Aquatic Wildlife

Screening-level exposure estimates for semi-aquatic wildlife exposed to bioaccumulative COPECs were assessed using deterministic dose rate models based on maximum exposure assumptions. Details for exposure parameters and model calculations are provided in Appendix D and summarized below.

The results of the canal-wide screening-level evaluation of wildlife indicate limited potential for adverse effects to semi-aquatic wildlife exposed to COPECs through ingestion pathways based on maximum exposure assumptions. HQs for modeled doses to mallard, great blue heron, and raccoon for any constituents with estimated doses exceeding TRVs are summarized below.

COPEC	Mallard		Great Blue Heron		Raccoon	
	HQ _{NOAEL}	HQ _{LOAEL}	HQ _{NOAEL}	HQ _{LOAEL}	HQ _{NOAEL}	HQ _{LOAEL}
Chromium	13.7	2.3	<1	<1	5.2	<1
Copper	3.2	1.6	<1	<1	<1	<1
Lead	31.7	3.2	25.9	2.6	7.4	<1
Mercury	16.4	8.2	12.6	6.3	6.2	3.7
Total LMW PAHs	1.5	<1	2.2	<1	<1	<1
Total HMW PAHs	60.4	6.0	90.3	9.0	2.9	<1
Total DDX	1.6	<1	2.5	<1	<1	<1

Based on maximum EPCs, estimated doses of chromium, copper, lead, mercury, total low molecular weight (LMW) PAHs, total high molecular weight (HMW) PAHs, and total DDX exceeded TRV_{NOAEL} values for at least one receptor. Estimated doses of each COPEC, except total LMW PAHs and total DDX, exceeded TRV_{LOAEL} values for at least one receptor based on maximum exposure assumptions.

6.2.3 Screening-Level Risk Characterization and SMDP

The screening-level exposure estimates presented in the previous section represent the most conservative exposure scenarios based on the comparisons of maximum COPEC concentrations to conservative ESVs. A preliminary characterization of potential risks is presented based on these conservative exposure assumptions to identify exposure

pathways that may warrant further evaluation. This preliminary characterization of potential risks is summarized below by receptor category.

Benthic Invertebrates

A conservative evaluation of measurement endpoints for benthic invertebrates indicates the potential for adverse ecological effects resulting from exposure to COPECs in bulk sediment within the Canal-Wide Area. Maximum concentrations of several VOCs, SVOCs, and total PAHs in bulk sediment exceeded conservative ESVs.

Evaluations of the spatial distributions of COPEC exceedances within the BAZ in the Canal-Wide Area indicate that maximum concentrations were generally observed at stations adjacent to outfall locations. Stations across transects away from outfall locations had relatively few exceedances of ESVs based on the screening-level evaluation. This finding indicates that benthic invertebrate exposure to concentrations greater than ESVs is spatially-limited to localized areas adjacent to current or historical outfalls.

Based on the screening-level exposure evaluation, a refined direct contact evaluation for bulk sediment is warranted as part of ERAGS Section 3.2 to further evaluate potential effects to benthic invertebrates associated with exposure to COPECs associated with the Canal-Wide Area. Exposure estimates for bulk sediment and pore water were refined using more representative EPCs and more representative ESVs (see Section 7.0).

Fish

Given that COPECs were not identified above ESVs in surface water, no unacceptable risks to the fish community in the Salem Canal were identified for the direct contact exposure pathway. ESVs were available for the relevant fraction (dissolved versus total) of each constituent detected in surface water.

The screening-level evaluation of dietary exposure to fish indicates limited potential for adverse effects through the ingestion of bioaccumulative COPECs in sediment-associated prey. Maximum estimated dietary concentrations of cadmium and total PCBs exceeded available LOEC benchmarks for growth endpoints. However, the cadmium and total PCB LOEC benchmarks for growth were also associated with NOEC growth endpoints for other growth measurements within the same ECOTOX studies (see Appendix D). Maximum estimated concentrations of mercury, zinc, and total DDX in benthic invertebrates exceeded dietary NOECs for fish (maximum HQ = 2.3), but were lower than respective LOECs for survival, growth, and reproduction. Dietary benchmarks for mercury likely overestimate exposure given that NOECs and LOECs were based on exposure to methylmercury and estimated concentrations in sediment-associated prey were based on total mercury concentrations. Further evaluation of dietary exposure to fish based on refined EPCs for cadmium, mercury, zinc, total DDX, and total PCBs is presented in the refined exposure evaluation (see Section 8.0).

In addition to ingestion of prey, demersal fish may also be exposed to COPECs in sediment through the incidental ingestion of sediment and pore water while foraging in sediment. Exposure via these routes is likely secondary and was not quantitatively evaluated in the SLERA.

Semi-Aquatic Wildlife

The results of deterministic dose rate models using maximum exposure assumptions indicate limited potential for adverse effects to semi-aquatic wildlife receptors. Of the bioaccumulative COPECs identified in the combined Canal-Wide and Former Seep Area sediment datasets, maximum EPCs resulted in estimated doses exceeding TRV_{NOAEL} values for chromium, copper, lead, mercury, LMW PAHs, HMW PAHs, and total DDX. Given that the conservative exposure assumptions of maximum EPCs do not accurately reflect representative exposure conditions for wildlife foraging throughout the Salem Canal, a refined exposure evaluation is warranted as part of ERAGS Section 3.2 to further evaluate potential dietary exposure to semi-aquatic wildlife associated with sediment-related COPECs. Refined deterministic exposure models incorporate EPCs that are more representative of likely EPCs resulting from foraging throughout the Salem Canal (see Section 7.0).

7.0 Refined Ecological Exposure Evaluation

SLERA Steps 1 and 2 were used to identify COPECs and evaluate ecological risk using the most conservative exposure assumptions. The conservative assumptions of the preliminary evaluation are intended to minimize the potential for excluding a COPEC that may actually cause an adverse effect; however, the most conservative exposure scenario more likely overestimates exposure and potential risk. Further refinement of exposure assumptions in ERAGS Section 3.2 is intended to focus the assessment on those COPECs and exposure pathways that may require further investigation. ERAGS Section 3.2 may also provide spatial context to areas of greater potential exposure that may be the focus of further investigation.

The elements of the ERAGS Section 3.2 COPEC refinement evaluation include the following:

- Refined direct contact evaluation for benthic invertebrate communities in the Former Seep Area and the Canal-Wide Area
- Refined deterministic dose rate models to evaluate potential exposure to semi-aquatic wildlife foraging throughout the Salem Canal (Former Seep Area and Canal-Wide Area).

7.1 Data Used to Refine Ecological Exposure Estimates

ERAGS Section 3.2 includes more representative exposure estimates for benthic invertebrates and semi-aquatic wildlife exposed to COPECs in bulk sediment and sediment pore water in the Salem Canal. The refined direct contact evaluation includes the development of more representative ecological benchmarks and EPCs, including the upper confidence limit of the mean (UCL_{mean}). The refined exposure evaluation for wildlife includes deterministic dose rate models based on UCL_{mean} EPCs to more accurately estimate exposure resulting from potential wildlife foraging throughout the Salem Canal. Datasets included in the refined exposure estimates and the methods refining the exposure estimates are presented in the following subsections.

7.1.1 Former Seep Area

Refined exposure estimates for benthic invertebrates in the Former Seep Area were calculated based on 2015 bulk sediment data to represent current ecological exposure conditions. As presented in the ECSM for the Former Seep Area (see Section 4.0), multiple lines of evidence indicate the potential for natural recovery processes in sediments, primarily biodegradation and burial for seep-related constituents (chlorobenzene, dichlorobenzene, benzene, aniline, n-nitrosodiphenylamine). Temporal analyses of the concentrations of seep-related constituents in the Former Seep Area presented in the *2017 Salem Canal Investigation Summary Report* indicated overall decreases in concentrations of key seep-related constituents over time. As illustrated in Figures 20a through 20c, statistically significant reductions in concentrations of primary seep-related constituents were observed in the BAZ between 2011 and 2015. Figures 10 and 11 illustrate the reduction in chlorobenzene and dichlorobenzene concentrations, respectively, estimated by kriging analysis using 2011 and 2015 datasets (AECOM and EHS Support, 2017). Given these observed reductions in the concentrations of seep-related constituents, the refined exposure estimates are based on 2015 bulk sediment data to reflect current exposure conditions in the Former Seep Area.

Temporal analyses of pore water data between sampling events were limited to qualitative comparisons that indicated general consistency in profile shape and magnitude of differences in concentrations (AECOM and EHS Support, 2017). Given that pore water concentrations remained generally consistent between sampling events, all available pore water data from multiple sampling events (2009, 2013, 2015, and 2016) were included in the refined exposure estimate (see Section 5.1.1). Consistent with the screening-level exposure evaluation, the refined exposure evaluation evaluated pore water from three intervals within the top 1-foot of sediment to evaluate exposure:

- 0 to 0.5-foot
- 0.5 to 0.75-foot
- 0.75 to 1.0-foot

7.1.2 Canal-Wide

The refined exposure estimate for the Canal-Wide Area was conducted based on the identical sediment dataset used in the screening-level exposure estimate (see Section 5.1.2).

7.2 Refined Exposure Estimate Methodology

The following subsections describe the methods used to refine the screening-level exposure evaluations based on the datasets identified in the previous section.

7.2.1 Refined Bulk Sediment Quality Benchmarks

Screening-level ESVs for bulk sediment were refined to develop Refined ESVs (RESVs) that provide more representative, yet protective estimates of chronic direct contact exposure to benthic invertebrates (see Table 26). The EqP approach described by (EPA, 2008) was used to develop organic carbon-normalized SQBs (SQB_{oc}) for organic COPECs in bulk sediment at the site. SQBs previously developed for use at Chambers Works were presented in DuPont CRG (2005) and the 2007 BEE (DuPont CRG, 2007). Documentation of the derivation methodology and the SQBs is provided in Appendix E.

SQB values represent concentrations of organic constituents in bulk sediment that, at equilibrium, would result in partitioning to sediment porewater at concentrations equivalent to NOEC water quality benchmarks (WQB_{NOEC}) based on constituent-specific organic carbon-water partitioning coefficients (K_{oc}) based on the following relationship:

$$SQB_{NOEC} = (f_{oc} \times K_{oc} \times WQB_{NOEC})$$

where:

SQB_{NOEC}	= Sediment quality benchmark based on NOEC aqueous toxicity data ($\mu\text{g}/\text{kg}$ dry weight sediment)
F_{oc}	= Fraction of organic carbon in sediment
K_{oc}	= Organic carbon-water partitioning coefficient (L/kg)
WQB_{NOEC}	= Water quality benchmark based on a chronic NOEC ($\mu\text{g}/\text{L}$)

SQB's were calculated based on chronic NOECs and the average TOC concentrations measured in the exposure areas:

- Former Seep Area: Average TOC of 3.5 percent.
- Canal-Wide Area: Average TOC of 1.5 percent, which represents the lowest average TOC concentration measured in Reach 1 (1.5 percent), Reach 2 (2.1 percent), and the Tidal Reach (1.6 percent).

The SQB for chlorobenzene used in previous assessments of benthic invertebrate exposure within the Former Seep Area was calculated using an EqP approach based on a chronic WQB derived from a theoretical quantitative structure-activity relationship (QSAR; see DuPont CRG, 2005). Assuming an average TOC concentration of 3.5 percent in the Former Seep Area, the QSAR-based SQB for chlorobenzene was 23 milligrams per kilogram (mg/kg) (dry weight). EPA (2008) calculated an organic carbon-normalized SQB for chlorobenzene of 570 mg/kg organic carbon based on the narcosis mode of toxic action, which is equivalent to 20 mg/kg at a TOC concentration of 3.5 percent. Given that the EPA (2008) benchmark is based on narcosis theory, as opposed to a theoretical QSAR endpoint, the EPA (2008) benchmark is used as the refined SQB in the Revised SLERA (see Appendix E).

The evaluation of benthic invertebrate exposure to PAHs was refined using EPA *Procedures for the Derivation of Equilibrium Partitioning Sediment Benchmarks for the Protection of Benthic Organisms: PAH Mixtures* (EPA, 2003a). The sum of Equilibrium Partitioning Sediment Benchmark Toxic Units (\sum ESBTUs) were calculated for each sample to reflect the additive toxicity of PAH mixtures as follows:

$$\sum ESBTU_{FCV,Total} = \sum_{i=1}^{13} \frac{C_{oc,PAHi}}{C_{oc,PAHi,FCVi}} \times UF$$

Where:

$\sum ESBTU_{FCV,Total}$	= Sum of ESBTUs for the PAH mixture (unitless)
C_{ocPAHi}	= Organic carbon normalized concentration of PAH <i>i</i> ($\mu\text{g}/\text{g}_{oc}$)
$C_{ocPAHi,FCVi}$	= Organic carbon normalized critical concentration concentration of PAH <i>i</i> based on the final chronic value ($\mu\text{g}/\text{g}_{oc}$)
UF	= Uncertainty factor to estimate the toxicity of total PAHs (based on 34 PAHs – 18 parent and 16 alkylated compounds) using measurements of 13 PAHs in bulk sediment in the Salem Canal.

$\sum ESBTU_{FCV,Total}$ values for PAH mixtures were calculated based on the concentrations of 13 PAHs and TOC measured in each sample. The $\sum ESBTU_{FCV,Total}$ was developed based on the analysis of 34 PAHs (EPA, 2003a). To account for differences in the estimation of $\sum ESBTU_{FCV,Total}$ based on the analysis of 13 PAHs in the Salem Canal, an uncertainty factor (UF) was applied in the calculation. A conservative UF of 6.78 was applied to the estimation of the summed toxic units based on the analysis of 13 PAHs ($\sum ESBTU_{FCV,13}$); this UF corresponds to the 80th percentile of the distribution of $\sum ESBTU_{FCV,Total} / \sum ESBTU_{FCV,13}$ evaluated in EPA (2003a). $\sum ESBTU_{FCV,Total}$ values less than 1 are considered to be protective of benthic invertebrate communities.

7.2.2 Exposure Point Concentrations

EPCs for COPECs in bulk sediment and sediment pore water were refined to include the UCL_{mean} . The EPA-developed software program ProUCL Ver. 5.1 was used to calculate EPCs based on the UCL_{mean} using the mode that considers results that are below the analytical detection limit. Analytical results below detection limits were input into ProUCL at the analytical detection limit and coded as non-detected results. UCL_{mean} values were calculated from each dataset and used to represent EPCs in the refined exposure estimation. UCL_{mean} EPCs were compared with refined ESVs and benchmark concentrations. Documentation of ProUCL calculations is provided in Appendix F.

7.2.3 Frequency of Detection

COPECs with detection frequencies of less than 5 percent were not evaluated further in the refined exposure estimation. Exclusion of these COPECs based on low detection frequencies is consistent with EPA guidance on the refinement of constituents in Step 3a of ERAGs (EPA, 2001c). Dietary exposure to detected constituents with the potential to bioaccumulate are evaluated using deterministic dose rate models regardless of detection frequency.

7.2.4 Comparison to Background Threshold Value

The refined exposure evaluation included comparisons to BTVs to assess whether site-related COPECs contribute to ecological exposure beyond regional conditions. Background concentrations may be used in the COPEC refinement step to effectively focus the ecological risk assessment (EPA, 2001c). The use of background datasets is also incorporated into NJDEP *Ecological Evaluation Technical Guidance* to refine the COPEC list, to assess whether COPECs may be site-related, and to evaluate site COPEC concentrations relative to regional COPEC concentrations (NJDEP, 2018). For the refined exposure estimates in the SLERA, maximum EPCs were compared to BTVs to evaluate site data in the context of regional conditions.

8.0 Refined Exposure Estimate and Risk Characterization

This section presents the results of the refined exposure estimates and risk characterizations for the Former Seep Area and the Canal-Wide Area investigated in the Salem Canal.

8.1 Former Seep Area

The refined exposure estimates and risk characterization for benthic invertebrates exposed to COPECs in sediment within the Former Seep Area are presented in the following subsections.

8.1.1 Refined Exposure Estimates

The screening-level exposure estimates for the benthic invertebrate community in the Former Seep Area (see Section 6.1.2) were refined using exposure assumptions that are more representative of current exposure conditions and revised ESVs that provide more representative, yet protective estimates of chronic direct contact exposure. COPECs with maximum concentrations exceeding preliminary ESVs in the screening-level exposure estimate are included in the refined exposure evaluation. Constituents identified as COPECs due to a lack of available ESVs in the screening-level exposure estimates are addressed as uncertainties (see Section 9.1); therefore, these COPECs are not included in the refined exposure estimates. The following subsections present the results of the refined exposure estimates for benthic invertebrates in Former Seep Area of the Salem Canal.

Bulk Sediment

The results of the refined exposure estimates for bulk sediment indicate limited potential for adverse effects to benthic invertebrates exposed to COPECs in the BAZ within the Former Seep Area. Refined estimates of benthic invertebrate exposure to COPECs in bulk sediment in the BAZ (0 to 0.5 feet) are summarized in Table 27. Of the seven VOCs with maximum concentrations exceeding preliminary ESVs, only methyl ethyl ketone had a UCL_{mean} concentration exceeding an ESV. The HQ based on the UCL_{mean} concentration (HQ_{UCL}) of methyl ethyl ketone was 1.2 (see Table 27). Refined EPCs for acetone, carbon disulfide, and chlorobenzene based on UCL_{mean} concentrations were lower than refined ESV benchmarks (see Table 27). Refined exposure estimates for SVOCs did not indicate any COPECs with refined EPCs exceeding refined ESVs. Maximum concentrations of six SVOC COPECs were lower than refined ESVs. Refined EPCs for bis(2-ethylhexyl)phthalate, carbazole, and phenol were lower than ESVs. In addition, the detection frequencies of bis(2-ethylhexyl)phthalate and 2-chlorophenol were less than 5 percent (see Table 27). Refined ESVs for total PAHs were lower than the preliminary ESV for total PAHs.

Figures 10 and 11 illustrate the spatially-limited extent of exceedances of refined ESVs for chlorobenzene and dichlorobenzenes, respectively, the primary seep-related COPECs. Estimated concentrations and the estimated area exceeding refined ESVs for chlorobenzene and dichlorobenzene were substantially lower based on the 2015 data when compared with 2011 data. Based on 2015 data, estimated exceedances of the refined ESV of 19.95 mg/kg for chlorobenzene in the BAZ are spatially-limited to an area defined by stations SCD-151, SCD-149, and SCD-150. This estimated area of exceedance is similar to the area defined by the SQB of 23 mg/kg used in previous exposure assessments (see Section 7.2.1 and Appendix E). Dichlorobenzene

concentrations estimated based on 2015 data did not exceed the refined ESV within the Former Seep Area.

Estimates of $\sum \text{ESBTU}_{FCV,Total}$ indicate that the potential for adverse effects to benthic invertebrates exposed to PAHs in the BAZ is limited. As illustrated in Figure 21, nine of 70 samples analyzed within the BAZ had $\sum \text{ESBTU}_{FCV,Total}$ values less than 1, indicating that concentrations of PAH mixtures are protective of benthic invertebrates from direct toxicity. $\sum \text{ESBTU}_{FCV,Total}$ values greater than 1 ranged from 1.1 to 8.6, indicating that the UF (6.78) applied to the estimated toxic units based on 13 PAHs ($\sum \text{ESBTU}_{FCV,13}$) to account for the potential toxicity of unmeasured PAH compounds contributed substantially to the number of samples with $\sum \text{ESBTU}_{FCV,Total}$ values greater than 1.

In samples collected from the 0.5 to 1-foot interval below the BAZ, only chlorobenzene exceeded RESVs based on maximum or refined EPCs (see Table 28). The UCL_{mean} EPC calculated for chlorobenzene was slightly greater than the revised ESV ($\text{HQ}=1.2$). Maximum concentrations of SVOCs were below refined ESVs, except for phenol and o-toluidine. However, phenol and o-toluidine were detected in less than 5 percent of samples. Refined EPCs based on the UCL_{mean} were lower than the ESV for total PAHs (see Table 28).

Estimates of $\sum \text{ESBTU}_{FCV,Total}$ for PAHs analyzed in the 0.5 to 1-foot interval were below 1 in 18 of 22 samples, indicating limited potential for adverse effects to benthic invertebrates (see Figure 21). Estimates of $\sum \text{ESBTU}_{FCV,Total}$ exceeding 1 in the 0.5 to 1-foot interval ranged from 1.1 to 2.5, indicating that the application of the UF (6.78) contributes substantially to the number of samples with $\sum \text{ESBTU}_{FCV,Total}$ values greater than 1.

Two organic constituents were excluded as COPECs in bulk sediment based on low detection frequencies (less than 5 percent of samples) during COPEC refinement: o-toluidine and phenol. Maximum detected concentrations of o-toluidine and phenol in sediment resulted in HQs of 1.9 to 2.4, respectively. Therefore, the magnitude of exceedance and distribution of detections of these organic COPECs were limited and did not materially affect the overall risk characterization.

Pore Water

The refined direct contact evaluation for pore water indicated limited exposure relative to maximum exposure scenarios. In pore water samples analyzed in the BAZ, only chlorobenzene and bis(2-ethylhexyl)phthalate were detected at concentrations exceeding ESVs. The refined EPC based on the UCL_{mean} chlorobenzene concentration only slightly exceeded the ESV, resulting in an HQ_{UCL} of 1.2 (see Table 29). Exposure to bis(2-ethylhexyl)phthalate is considered negligible in pore water within the BAZ due to its low detection frequency (3 percent). PAHs were not detected in pore water in the BAZ at concentrations exceeding ESVs.

In pore water samples from intervals below the BAZ, exposure is limited to concentrations of chlorobenzene that slightly exceed the ESV based on EPCs refined based on the UCL_{mean} . The refined EPC for chlorobenzene in the 0.5-0.75-foot interval slightly exceeded the ESV ($\text{HQ}_{\text{UCL}}=2.4$); however, refined EPCs for other COPECs in this interval were less than the ESV (2-chlorophenol and aniline) or had a detection frequency lower than 5 percent [bis(2-ethylhexyl)phthalate; see Table 30].

8.1.2 Refined Risk Characterization and SMDP

The following subsections present the refined risk characterization and SMDP for benthic invertebrates exposed to COPECs in the Former Seep Area.

Benthic Invertebrates

The evaluation of current exposure based on the refined exposure estimates for bulk sediment and pore water data collected in 2015-2016 indicates limited, localized potential for adverse effects to benthic invertebrates within the Former Seep Area. Temporal comparisons of concentrations of seep-related COPECs in bulk sediment within the Former Seep Area indicate that significant reductions in seep-related constituent concentrations in bulk sediment from 2011 to 2015 have reduced overall exposure to benthic invertebrates.

Under current exposure conditions, the greatest potential for adverse effects to benthic invertebrates is associated with exposure to chlorobenzene in pore water. Chlorobenzene was the most frequently detected constituent in pore water and exceedances of ESVs were identified at individual pore water sampling stations. Given the uncertainty associated with exposure to chlorobenzene and other seep-related COPECs in the Former Seep Area, continued monitoring of exposure conditions within the BAZ is appropriate. Consistent with the ECSM and supported by temporal comparisons of bulk sediment data, reductions in exposure concentrations of chlorobenzene and other seep-related COPECs are anticipated through natural recovery processes primarily associated with biodegradation and burial.

Based on the refined analysis of bulk sediment and pore water data, exposure to PAHs is not likely to result in adverse effects to benthic invertebrates within the Former Seep Area. EqP modeling of PAH concentrations in the BAZ indicate limited $\sum \text{ESBTU}_{FCV, Total}$ values exceeding 1. For those samples with $\sum \text{ESBTU}_{FCV, Total}$ values exceeding 1, estimated values were greatly influenced by the application of an UF to account for unmeasured PAHs. Therefore, the site-specific applicability of this UF in the calculation of toxic units for PAHs in the Former Seep Area is a critical uncertainty in the refined exposure estimate.

A limited number of PAHs was detected in pore water samples within the BAZ, indicating that $\sum \text{ESBTU}_{FCV, Total}$ values calculated based on bulk sediment (including the UF) may over-estimate potential PAH exposure in pore water. Only naphthalene and fluorene were detected in at least one pore water sample collected within the BAZ; maximum concentrations of both COPECs were below FCVs derived by EPA (2003a). The absence of detectable PAHs in pore water at concentrations exceeding ESVs indicates a limited potential for PAH mixtures to adversely impact the benthic invertebrate community in the Former Seep Area.

Scientific Management Decision Point

While the refined exposure estimates indicate a limited potential for adverse effects to benthic invertebrates in the Former Seep Area, the information is not adequate to support risk-management decisions at this point. Continued monitoring of exposure conditions within the BAZ is appropriate to further support the weight-of-evidence evaluation of natural recovery in sediment, consistent with MNR Framework. Recommendations for future monitoring within the Former Seep Area have been presented in the *2017 Salem Canal Investigation Summary Report* (AECOM and EHS Support, 2017).

8.2 Canal-Wide Investigation

Refined exposure estimates and risk characterizations for benthic invertebrates and semi-aquatic wildlife exposed to COPECs in sediment within the Canal-Wide Area are presented in the following subsections.

The refined exposure evaluation for the Canal-Wide Area also included an assessment for the presence of hot spots, which are well-defined areas where constituent levels are substantially elevated above ecological screening criteria or background concentrations (NJDEP, 2018). NJDEP (2018) provides guidance for the identification of hot spots, which are generally defined by 1) frequency of detection above ecological screening criteria or background concentrations is elevated compared to surrounding site samples, and 2) the magnitude of the exceedance is substantial (e.g., greater than 10 times the ecological screening criteria or background concentrations). The potential presence of hot spots in the Canal-Wide Area were evaluated based on the general criteria provided in NJDEP (2018).

8.2.1 Refined Exposure Estimates

Refined exposure estimates are presented below for benthic invertebrates exposed to VOCs, SVOCs and metals in sediment within Reach 1, Reach 2 (outside of the Former Seep Area), and the Tidal Reach. Given the limited number of samples within each reach, benthic invertebrate exposure estimates for pesticides and PCBs were refined based on data from all three site reaches. Refined exposure estimates for fish and semi-aquatic wildlife include evaluation of the combined datasets for the Canal-Wide Area and Former Seep Area.

Benthic Invertebrates

Exposure estimates for benthic invertebrates were refined using assumptions that are more representative of average conditions and revised ESVs that provide more representative, yet protective estimates of chronic direct contact exposure. COPECs with maximum concentrations exceeding preliminary ESVs in the screening-level exposure estimate are included in the refined exposure evaluation. Constituents identified as COPECs due to a lack of available ESVs in the screening-level exposure estimates are addressed as uncertainties (see Section 9.1); therefore, these COPECs are not included in the refined exposure estimates. The following subsections summarize refined exposure estimates for benthic invertebrates by site reaches.

Reach 1

Refined bulk sediment exposure estimates for benthic invertebrates in the BAZ (0 to 0.5 feet) and the 0.5 to 1-foot interval within Reach 1 are summarized in Tables 32 and 33, respectively. Figure 22 illustrates the location of exceedances of ESVs and BTVs in Reach 1 based on the refined exposure evaluation.

The results of the refined exposure estimate for the BAZ indicates that, except for pesticides, PCBs, and select metals, refined EPCs were below ESVs or maximum EPCs were below BTVs (see Table 32). The maximum concentration of 2-methylnaphthalene was below the refined ESV and refined EPCs for total PAHs were lower than the preliminary ESV. Refined EPCs for metals with maximum concentrations exceeding preliminary ESVs were below ESVs, except for mercury, silver, and zinc (see Table 32). HQs for mercury, silver, and zinc based on refined EPCs and ESVs ranged from 1.3 to 1.5. HQs for other metals based on refined EPCs and ESVs, without consideration of

background concentrations, ranged from < 1 to 4.3 (lead). Further refinement of pesticides and PCBs are presented below on a canal-wide basis.

Estimates of $\sum \text{ESBTU}_{FCV, Total}$ based on PAH concentrations in samples from the BAZ indicate a limited potential for adverse effects to benthic invertebrates exposed to PAHs. As illustrated in Figure 21, $\sum \text{ESBTU}_{FCV, Total}$ values for 10 of 18 samples analyzed exceeded 1. $\sum \text{ESBTU}_{FCV, Total}$ values greater than 1 ranged from 1.2 to 13.9; however, only two samples had $\sum \text{ESBTU}_{FCV, Total}$ values greater than 2.5. These results indicate that the UF (6.78) applied to the estimated the potential toxicity of unmeasured PAH compounds contributes substantially to the number of samples with $\sum \text{ESBTU}_{FCV, Total}$ values greater than 1.

In samples collected from the 0.5 to 1-foot interval in Reach 1, PAHs and select metals had refined EPCs exceeding refined ESVs or BTVs (see Table 33); further refinement of exposure estimates for pesticides and PCBs are presented separately using data from the entire canal-wide exposure area. Refined EPCs for total PAHs slightly exceeded ESVs, resulting in $\text{HQ}_{\text{SUC}}L$ of 1.1 and 1.3. $\sum \text{ESBTU}_{FCV, Total}$ values for PAHs were less than 1 in 11 of 16 samples. The maximum $\sum \text{ESBTU}_{FCV, Total}$ value was 13.8; however, four of the five values exceeding 1 were less than 3.5 (see Figure 21). Refined EPCs for antimony, lead, and mercury exceeded ESVs, with $\text{HQ}_{\text{SUC}}L$ ranging from 2.8 (antimony) to 16.4 (lead).

Additional sediment characterization sampling conducted in 2018 indicates that elevated mercury concentrations at stations adjacent to historical Outfall Q are limited to sampling intervals below the BAZ. Sediment mercury concentration were greatest in Reach 1 in the 0.5-1-foot interval samples collected at SC-204 and SC-205 (Figure 22); mercury concentrations within the BAZ at SC-204 and SC-205 were less than two times background concentrations. Mercury concentrations in 2018 characterization samples collected within the BAZ and the 0.5-1-foot interval stations adjacent to SC-204 and SC-205 (SC-257 through SC-260) were below the mercury BTV established for the Reference Reach.

Maximum sediment mercury concentrations in Reach 1 were less than 10 times the BTV and concentrations in the BAZ and 0.5-1-foot sampling intervals at adjacent sampling stations were below BTVs. Therefore, these areas of elevated COPEC concentrations are not considered hot spots based on the general criteria provided NJDEP (2018). These areas represent well-defined, spatially-limited areas of elevated exposure to benthic invertebrates adjacent to outfalls.

Reach 2

The refinement of exposure estimates in Reach 2 was limited primarily to metals. As previously discussed, a limited number of VOCs and SVOCs was analyzed in Reach 2 outside of the Former Seep Area. A detailed discussion of the refined exposure estimate for the Former Seep Area is provided in Section 8.1. Figure 23 illustrates the location of exceedances of ESVs and BTVs in Reach 2 based on the refined exposure evaluation.

Refined exposure estimates for the BAZ in Reach 2 indicate limited potential for adverse effects for select metals. Refined EPCs for eight metals exceeded refined ESVs (see Table 34); $\text{HQ}_{\text{SUC}}L$ for these metals ranged from 1.3 (iron) to 4.7 (lead). For other metals, refined EPCs were below ESVs or maximum concentrations were below BTVs (see Table 34). $\sum \text{ESBTU}_{FCV, Total}$ values for the two PAH samples analyzed in Reach 2 outside of the Former Seep Area only slightly exceeded 1, with values ranging from 1.8 and 2.1 (see Figure 21). Considering the application of the conservative UF in the estimation of

\sum ESBTU_{FCV,Total}, the potential for adverse effects due to exposure to PAHs in Reach 2 outside of the Former Seep Area is not likely. Refined exposure estimates for pesticides were evaluated on a canal-wide basis; however, it is important to note that maximum concentrations of pesticides detected within Reach 2 did not exceed refined ESVs (see Table 34).

Refined exposure estimates for the 0.5 to 1-foot interval in Reach 2 outside of the Former Seep Area indicated greater COPEC concentrations than the 0-0.5-foot interval; however, these concentrations are below the BAZ where the greatest ecological exposure occurs. For VOCs, maximum concentrations of chlorobenzene and xylenes exceeded refined ESVs, resulting in HQs of 11 and 7.4, respectively (see Table 35). Maximum concentrations of 1,2-dichlorobenzene, biphenyl and total PAHs exceeded ESVs. Refined EPCs could not be calculated for these VOC or SVOC COPECs due to limited sample size within Reach 2.

\sum ESBTU_{FCV,Total} values were greater than 1 in one (\sum ESBTU_{FCV,Total} = 2.3) of two PAH samples analyzed in the 0.5 to 1-foot interval (see Figure 21). Maximum concentrations of Endosulfan I exceeded the refined ESV; the evaluation of pesticide exposure was further refined on a canal-wide basis. Refined EPCs exceeded ESVs and maximum EPCs exceeded BTVs for 10 metals in the 0.5-1-foot sampling interval (see Table 35). HQ_{SUCL} for these metals ranged from 1.2 (aluminum) to 13.8 (cadmium). Maximum EPCs for arsenic, iron, and nickel were below BTVs.

Additional sediment characterization sampling conducted in 2018 indicates that elevated mercury and total PAH concentrations at stations adjacent to select historical outfalls in Reach 2 are spatially-limited. Elevated sediment mercury concentrations were observed in samples collected adjacent to historical Outfalls D, E, F, H, and M, with the maximum mercury concentration measured in the BAZ (2.41 mg/kg) observed at SC-200 adjacent to historical Outfall M (Figure 23). Mercury concentrations in samples collected from the BAZ at stations adjacent to SC-200 (SC-199, SC-261, and SC-262) were less than 1.5 times the BTV. 2018 sediment characterization samples collected from the BAZ at stations adjacent to historical Outfalls D, E, F, and H (SC-263 through SC-267) contained mercury concentrations that were lower than the BTV, except for SC-265 that contained a mercury concentration in the BAZ that was approximately 2 times the BTV. Mercury concentrations in the 0.5-1-foot interval at these stations were lower than the BTV, except for SC-266 (Figure 23). Elevated total PAH concentrations at SC-200 located adjacent to historical Outfall M were spatially bounded by total PAH concentrations below the BTV in the BAZ and 0.5-1-foot interval at adjacent stations SC-199, SC-262, and SC-261 (Figure 23). \sum ESBTU_{FCV,Total} values at stations SC-261 and SC-262 were less than 1, indicating concentrations of PAH mixtures that are protective of benthic organisms.

Maximum mercury and total PAH concentrations within the BAZ and the 0.5-1-foot interval in Reach 2 were less than 10 times BTVs and ESVs and were spatially bounded by samples from adjacent stations that were below ESVs or BTVs. Therefore, these areas of elevated mercury and total PAH concentrations are not considered hot spots based on the general criteria provided in NJDEP (2018). These areas represent well-defined, spatially-limited areas of elevated exposure to benthic invertebrates adjacent to historical outfalls.

Tidal Reach

Refined bulk sediment exposure estimates for benthic invertebrates in the BAZ (0 to 0.5 foot) and the 0.5 to 1-foot interval within Tidal Reach are summarized in Tables 36 and

37, respectively. Figure 24 illustrates the location of exceedances of ESVs and BTVs in the Tidal Reach based on the refined exposure evaluation.

The results of the refined exposure estimate for bulk sediment in the BAZ indicate that the potential for adverse effects is limited primarily to select metals (see Table 36). Refined exposure estimates exceeded ESVs and maximum EPCs exceeded BTVs for eight metals. $HQ_{S_{UCL}}$ for these metals ranged from 1.5 (antimony) to 20.1 (chromium). For other metals, refined EPC were below ESVs or maximum EPCs were below BTVs. The maximum concentration of 4-methylphenol exceeded the refined ESV ($HQ=2.1$). Maximum concentrations of 1,2-dichlorobenzene, 1,4-dichlorobenzene, 2-methylnaphthalene, Endosulfan I, and beta-BHC were less than refined ESVs. Refined EPCs for total PAHs exceeded the preliminary ESV, resulting in an $HQ = 2.4$. $\sum ESBTU_{FCV, Total}$ values were greater than 1 for seven of 16 samples; however, all but one sample had an $\sum ESBTU_{FCV, Total}$ value less than 3.5. (see Figure 21).

The refined exposure estimates for the 0.5 to 1-foot interval indicated greater COPEC concentrations relative to the BAZ; however, these concentrations are below the BAZ where the greatest ecological exposure occurs. Methyl ethyl ketone exceeded the ESV in one of 13 samples at a concentration slightly exceeding the ESV ($HQ=1.6$; see Table 37). Refined EPCs exceeded ESVs and maximum EPCs exceeded BTVs for seven metals; $HQ_{S_{UCL}}$ for these metals ranged from 1.1 (mercury) to 10.1 (chromium). Refined EPCs were lower than ESVs or maximum EPCs were lower than BTVs for other metals (see Table 37). Refined EPCs for total PAHs were comparable to ESVs, resulting in $HQ_{S_{UCL}}$ of 1.0 and <1 . $\sum ESBTU_{FCV, Total}$ values were greater than 1 for four of 16 samples, with $\sum ESBTU_{FCV, Total}$ values ranging from 1.1 to 4.9 (see Figure 21).

Additional sediment characterization sampling conducted in 2018 indicates that elevated COPEC concentrations at specific stations adjacent to outfalls in the Tidal Reach are spatially-limited. Sediment chromium concentrations were greatest in surficial samples collected at SC-237 and SC-272 (Figure 24). Chromium concentrations decreased with depth at these stations and were lower in surface intervals at adjacent stations; surface concentrations at SC-271, the westernmost sampling station in the Salem Canal were less than two times the BTV (Figure 24). Similar to chromium, the maximum concentrations of arsenic and lead in the surface interval at SC-231 adjacent to Outfall 013 were spatially bounded by adjacent samples (SC-268, SC-230, and SC-228). Arsenic and lead concentrations in the BAZ and the 0.5-1-foot intervals at these stations were comparable to or below BTVs (Table 14). Elevated total PAH concentrations observed at in surface sampling intervals at SC-236 were spatially bounded by samples collected in 2018 at SC-269 and SC-270; total PAH concentrations within the BAZ and the 0.5-1-foot sampling interval were below the ESV of 4,000 $\mu\text{g}/\text{kg}$. Furthermore, $\sum ESBTU_{FCV, Total}$ values in these samples were less than 1, indicating concentrations of PAH mixtures that are protective of benthic organisms.

Maximum arsenic, lead, chromium, and total PAH concentrations in surface intervals within the Tidal Reach were less than 10 times BTVs or ESVs and concentrations at some adjacent sampling stations were below ESVs or BTVs. Therefore, these areas of elevated COPEC concentrations are not considered hot spots based on NJDEP (2018). These areas represent well-defined, spatially-limited areas of elevated exposure to benthic invertebrates adjacent to outfalls.

Canal-Wide Pesticides and PCBs

Refined exposure estimates for pesticides and PCBs were evaluated using all data from the Canal-Wide Area to enable sufficient data points to calculate EPCs based on

UCL_{mean} concentrations. Tables 38 and 39 summarize the results of the refined exposure estimates for pesticides and PCBs based on all Canal-Wide data.

The results of the canal-wide evaluation of pesticide and PCB exposure to benthic invertebrates indicate limited potential for adverse effects. Within the BAZ, maximum concentrations of all pesticides with refined ESVs were lower than refined ESVs. For pesticides without refined ESVs, exposure estimates were consistent with the screening-level evaluation (see Table 38). Maximum concentrations of 4,4'-DDD, 4,4'-DDE, total DDX, and heptachlor epoxide were greater than conservative ESVs, resulting in HQs ranging from 1.1 to 4. However, the detection frequencies for most pesticides were relatively low (less than 50 percent). The refined EPC for total PCBs was lower than the conservative ESV (see Table 38).

In the 0.5 to 1-foot interval, a limited number of pesticides and total PCBs was retained in the refined exposure estimate. The maximum concentrations of total DDX and lindane and the refined EPCs for Endosulfan I and total PCBs exceeded ESVs. HQs based on maximum exposure concentrations for total DDX and lindane were 1.6 and 7.7, respectively. HQs based on refined EPCs for Endosulfan I and total PCBs and conservative ESVs were 1.3 and 3.4, respectively. Concentrations of other pesticides measured in site reaches were below refined ESVs or were within the range of concentrations observed in the upstream Reference Reach (see Table 39).

Fish

No further evaluation of direct surface water exposure to fish was conducted based on the findings of the screening-level risk characterization (see Section 6.2.3), which indicated that constituents detected in surface water pose negligible direct contact risk to fish. Potential dietary exposure to fish was evaluated based on comparisons of dietary endpoints for fish survival, growth, and reproduction to estimated concentrations in benthic invertebrates based on UCL_{mean} sediment concentrations. Estimated concentrations of cadmium, mercury, and total PCBs in benthic invertebrates were below available dietary NOECs for fish survival, growth, and reproduction (Table 40). The estimated concentration of zinc in benthic invertebrates exceeded NOECs for growth and survival, resulting in a maximum $HQ_{NOEC} = 1.6$; however, the estimated zinc concentration was substantially below the LOEC for growth. Refined benthic invertebrate EPCs for cadmium and total PCBs exceeded available dietary LOECs for growth; however, the refined EPCs were below growth NOECs. A refined EPC could not be calculated for total DDX, due the low number of detected concentrations of DDT and its metabolites in sediment.

Semi-Aquatic Wildlife

Refined exposure estimates for semi-aquatic wildlife calculated using UCL_{mean} sediment concentrations as EPCs indicate minimal potential for adverse effects to representative receptors that may forage throughout the Salem Canal. HQs for modeled doses to mallard, great blue heron, or raccoon for COPECs with estimated doses exceeding high or low TRVs are summarized below (see Appendix D):

COPEC	Mallard		Great Blue Heron		Raccoon	
	HQ _{NOAEL}	HQ _{LOAEL}	HQ _{NOAEL}	HQ _{LOAEL}	HQ _{NOAEL}	HQ _{LOAEL}
Chromium	2.7	<1	<1	<1	1.0	<1
Lead	<1	<1	<1	<1	<1	<1
Mercury	<1	<1	<1	<1	<1	<1
Total LMW PAHs	<1	<1	<1	<1	<1	<1
Total HMW PAHs	<1	<1	<1	<1	<1	<1

The results of the refined exposure evaluation indicate minimal potential for adverse effects to mallard exposed to chromium through ingestion pathways. The estimated daily dose of chromium to mallard based on the UCL_{mean} sediment concentration for the Canal-Wide Area resulted in an HQ_{NOAEL} of 2.7; the estimated daily dose of chromium to mallard was lower than the LOAEL-based TRV ($HQ_{LOAEL} < 1$). The estimated daily dose of chromium to raccoon was equivalent to the NOAEL TRV, but lower than the LOAEL TRV. The estimated daily dose of chromium to great blue heron was below the TRV_{NOAEL} and TRV_{LOAEL} values based on the refined EPC. Refined doses of total HMW PAHs were below TRV_{NOAEL} values for each receptor. Refined exposure estimates for wildlife are considered to be conservative based on the assumption that receptors would forage entirely within the Canal-Wide Study Area.

No further refinement of potential wildlife exposure to total DDX was conducted due to the limited number of detections of DDX compounds. However, the limited detection frequency and relatively low concentrations of DDX compounds indicate that adverse effects to wildlife are not likely. As discussed in Section 6.2.2, estimated daily doses of total DDX slightly exceeded the TRV_{NOAEL} value for mallard and great blue heron, resulting in HQs of 1.6 and 2.5, respectively. Estimated total DDX doses did not exceed TRV_{LOAEL} values for either receptor in the screening-level evaluation. Refinement of the screening-level evaluation for total DDX using refined EPCs was not possible due to three or fewer samples containing detected concentrations of DDX compounds (see Table 38), which precluded the calculation of refined UCL_{mean} concentrations. Given the limited exceedances of TRV_{NOAEL} values based on the maximum exposure scenario presented in the screening-level exposure evaluation and the low detection frequencies of DDX compounds in the BAZ, adverse effects to wildlife are not likely.

8.2.2 Refined Risk Characterization and SMDP

Refined exposure estimates for bulk sediment for the Canal-Wide Area indicate limited, localized potential for adverse effects to benthic invertebrates and negligible potential for adverse effects to semi-aquatic wildlife potentially foraging throughout the Salem Canal. The refined risk characterization is based on estimated exposure within the BAZ where the greatest potential for ecological exposure is present.

Benthic Invertebrates

The results of the refined exposure estimate indicate a limited potential for adverse effects to the benthic invertebrate community in the Canal-Wide Area. Potential

exposure to benthic invertebrates was greatest for select metals with elevated concentrations at a limited number of sampling stations located adjacent to outfalls in Reach 2 and the Tidal Reach. Based on the refined exposure evaluation, the greatest potential exposure to benthic invertebrates was associated with chromium and lead concentrations in the Tidal Reach. As discussed in the screening-level exposure evaluation (see Section 6.2.2), maximum EPCs for these metals were influenced substantially by results at a limited number of stations in the Tidal Reach [SC-237-TRT2M(0-0.5) for chromium; SC-231-Out13(0-0.5) and SC-239-Out11(0-0.5) for lead]. In Reach 2, benthic invertebrate exposure was greatest for lead and mercury, primarily driven by elevated concentrations in the BAZ at two historical outfall stations [SC-187-OutC-(0-0.5) and SC-200-OutM-(0-0.5)].

Exposure to organic COPECs is not likely to result in adverse effects to benthic invertebrate communities in the Canal-Wide Area. Exposure to VOCs and SVOCs at concentrations exceeding ESVs or refined ESVs were limited in the Canal-Wide Area. Overall exposure to total PAHs was below or slightly exceeding ESVs in the refined exposure evaluation. Estimates of potential PAH partitioning to pore water based on the $\sum \text{ESBTU}_{FCV, Total}$ indicated a limited number of stations in the Canal-Wide Area with the potential for adverse effects to benthic invertebrates. However, $\sum \text{ESBTU}_{FCV, Total}$ values at most stations did not substantially exceed 1 and were likely biased high by the application of an UF to conservatively account for unmeasured PAHs in the EqP model. The refined exposure evaluation for pesticides and PCBs indicated limited potential for adverse effects.

Additional sediment characterization sampling conducted in 2018 further defined the extent of spatially-limited areas of elevated exposure to benthic invertebrates adjacent to outfalls. Elevated concentrations of arsenic (Tidal Reach), chromium (Tidal Reach), lead (Tidal Reach), mercury (Reach 1 and 2), and total PAHs (Reach 2 and Tidal Reach) identified at stations adjacent to outfalls during the 2016 canal-wide sediment characterization sampling were spatially bounded by lower concentrations in 2018 characterization samples. COPEC concentrations in samples collected at stations within these spatially-limited areas of elevated exposure were generally lower within the BAZ relative to the 0.5-1-foot interval, indicating that elevated concentrations may be related to historical outfall discharge.

While localized exposure to COPECs, particularly metals, may occur at concentrations exceeding ESVs in spatially-limited areas adjacent to outfalls, benthic invertebrate exposure to COPECs within the BAZ at most stations in the Canal-Wide Area is not likely to result in adverse community-level effects. The potential for adverse effects within the BAZ at outfall locations will likely be reduced over time. Many historical outfalls have been decommissioned by the installation of the perimeter SPB and the continued deposition of sediment from upstream areas will facilitate natural recovery (see Section 3.1; Table 1). Lower concentrations observed in the BAZ relative to the 0.5-1-foot interval at stations located adjacent to outfalls may indicate that sediment containing lower COPEC concentrations has been deposited in these areas following the decommissioning of outfalls.

Fish

The exposure evaluation for fish indicates minimal potential for adverse effects to fish exposed to surface water through direct contact pathways and dietary items through ingestion pathways. The findings of the screening-level exposure evaluation indicate that constituents detected in surface water pose negligible direct contact risk to fish (see

Section 6.2.3). Estimated dietary concentrations of cadmium, mercury, zinc, and total PCBs based on UCL_{mean} sediment concentrations and conservative sediment-benthic invertebrate BSAFs indicate minimal risk based on available NOECs derived for survival, growth, and reproduction endpoints (Table 40). Estimated concentrations of cadmium, mercury, and total PCBs in benthic invertebrates were below dietary NOECs derived for fish survival, growth, and reproduction. Refined benthic invertebrate EPCs for cadmium and total PCBs exceeded available dietary LOECs for growth. However, these LOECs were derived from single studies as compared to multiple studies included in the derivation of NOECs (see Appendix D). Further, the single studies used to estimate LOECs for cadmium and total PCBs had corresponding growth endpoints at exposure concentrations equivalent to the LOEC that did not result in adverse growth effects. The estimated concentration of zinc in benthic invertebrates slightly exceeded NOECs for growth and survival (maximum $HQ_{NOEC} = 1.6$); however, the estimated zinc concentration was substantially lower than the derived zinc LOEC for growth. As previously stated, a refined EPC was not calculated for total DDX due the low number of detected concentrations of DDT and its metabolites in sediment samples. However, given the low frequency of detection of these compounds in sediment, dietary exposure to total DDX is not likely to result in adverse effects to fish in the Salem Canal.

Semi-Aquatic Wildlife

The results of the refined exposure evaluation presented in the previous sections indicate negligible risk to semi-aquatic wildlife that may potentially forage throughout the Salem Canal. Deterministic dose rate models for semi-aquatic wildlife foraging exclusively at EPCs based on UCL_{mean} concentrations resulted in minimal exceedances of the conservative low TRV and no exceedances of the high TRV. The estimated daily doses calculated by the models likely overestimate exposure given that receptors are not likely to forage exclusively in the Salem Canal due to the poor-quality habitat available along the developed riparian adjacent to Chambers Works.

Scientific Management Decision Point

The refined exposure estimates for bulk sediment for the Canal-Wide Area indicates limited, localized potential for adverse effects to benthic invertebrates and negligible potential for adverse effects to fish and semi-aquatic wildlife potentially foraging throughout the Salem Canal. While the refined exposure estimates indicate limited potential for adverse effects to benthic invertebrates at select stations adjacent to outfalls, there is adequate information to conclude that overall risks to the ecological receptors are negligible in the Canal-Wide Area; therefore, there is no need for remediation based on ecological risk.

9.0 Uncertainty

An uncertainty analysis was performed to identify assumptions and procedures that may result in uncertainty in the estimation of exposure or the characterization of risk.

Uncertainty in the SLERA is assessed with respect to the following:

- Exposure and effects assessment
- Risk characterization

Assumptions and other factors that tend to overestimate, underestimate, or have an unknown effect on the findings of the primary phases of the SLERA are presented and discussed in the following subsections.

9.1 Exposure and Effects Assessment

Sources of uncertainty related to the exposure assessment include (1) sediment quality benchmarks and (2) absorption from ingested doses.

9.1.1 Screening and Sediment Quality Benchmarks

The ecological screening levels presented in this SLERA are conservative and directed at identifying the presence/absence of risk of adverse ecological harm. However, the screening benchmarks do not reflect site-specific conditions such as the effects of habitat properties or potentially antagonistic or synergistic effects between different compounds.

Refined ESVs for select constituents were derived using a combination of site-specific data and laboratory data. Although intended to reflect a representative exposure scenario, inputs to the derivation of the revised ESVs were conservative. Because of the conservatism of the model used to develop the refined ESVs, the derived ESVs are deemed adequate and are not likely to underestimate exposure.

Uncertainty is introduced into the risk assessment process when insufficient toxicological data exist to develop benchmarks. Detected constituents lacking established criteria cannot be quantitatively assessed; exposure to these constituents must be considered an uncertainty in the SLERA.

The uncertainty associated with insufficient toxicological data is low and is not likely to influence the findings and conclusions of the Revised SLERA due to low detection frequencies of constituents without ESVs. Table 41 summarizes the constituents for which ESVs were not available. Detection frequencies were low (<5 percent) for VOCs, SVOCs, and two of three pesticides without ESVs in the Canal-Wide Area. As expected, detection frequencies were high for naturally occurring metals in sediment in the Canal-Wide Area. Although metals lacked ESVs, background concentrations from the upstream Reference Reach were available to evaluate the constituents. In the Former Seep Area, detection frequencies of VOCs and SVOCs without ESVs were less than 15 percent, with most constituents not detected in samples from the Former Seep Area (see Table 41). Given the limited detection frequencies of constituents without ESVs, it is not likely that the uncertainty associated with these constituents would drive risk or alter the conclusions presented in the Revised SLERA.

Toxicological information is available for the primary constituents (e.g., metals, pesticides, PCBs) that have been demonstrated to cause adverse ecological effects. The influence of the uncertainties of insufficient toxicological information on the

evaluation of ecological exposure is unknown, but the lack of toxicological benchmarks may underestimate risk.

9.1.2 Constituent Bioavailability

Chemical analyses of surface water and bulk sediment measured the total levels of the COPECs rather than the bioavailable toxic forms. The availability and assessment using total concentrations assume that the entire fraction is bioavailable and toxic. This is likely a conservative assumption that varies from constituent to constituent. It is also likely that, to some degree, COPECs adsorb to fine-grained particles and/or complex with chemical agents and organic ligands in bulk sediments. Such actions may change the chemical speciation of the COPEC to a less toxic form or reduce the concentrations of bioavailable chemicals.

The use of the total concentrations to estimate exposure does not consider these changes in speciation or reductions in toxicity and, therefore, likely overestimates risk when compared to toxicological benchmarks derived from more bioavailable and toxic forms. The EqP assessments used to develop refined ESVs for organic constituents likely reduced uncertainty associated with bioavailability.

Under or over-estimating risk can also occur because of differences in absorption rates observed at the site and laboratory studies used to determine uptake. In this regard, 100 percent bioavailability (relative to the test compounds in the underlying toxicity studies) was assumed at the site. Thus, if the absorption observed at the site is the same as that observed in the laboratory test, then the prediction of adverse effects will be accurate. If absorption at the site is greater, the prediction of adverse effects may be underestimated. However, if the absorption of the chemical at the site is lower than observed in the laboratory study, exposure will be overestimated. The assumption made in this SLERA that site-related compounds are 100 percent bioavailable is more likely to overestimate exposure to COPECs in sediments. It is assumed, however, that the fraction of COPECs observed in sediment pore water is bioavailable. The effects on the SLERA results associated with the assumptions regarding uptake and absorption are uncertain although they are likely to overestimate risk.

Exposures to ecological receptors at this site involve more than one type of contaminant. This raises the possibility that synergistic or antagonistic interactions might occur. However, data are generally not adequate to permit any quantitative adjustment in toxicity values or risk calculations based on interactions between different compounds. If it is the case that any of the COPECs act by a similar mode of action, total risks could have been higher than estimated. Conversely, if the COPECs act antagonistically, total risks could have been lower than estimated.

9.1.3 Deterministic Exposure Models

There is inherent uncertainty in estimating potential exposure to wildlife using the deterministic dietary models presented in the Revised SLERA. Unlike probabilistic exposure modeling, deterministic models do not account for the variability in the selection of receptor-specific exposure factors or exposure variables. To minimize the uncertainty in selecting static exposure parameters and exposure variables, the models were parameterized with conservative exposure assumptions intended to minimize the probability of underestimating exposure to wildlife via ingestion pathways. Key uncertainties associated with model parameters that may overestimate, underestimate, or have an unknown effect on the estimation of exposure to wildlife receptors are

discussed in detail in Appendix D. Given the conservative parameters included in the deterministic exposure models, it is not likely that dietary exposures to wildlife were underestimated in the Revised SLERA.

9.2 Risk Characterization

The application of hazard quotients to quantify potential ecological risk has certain limitations although the EPA recommends the approach for the screening-level risk calculation. One of the advantages is that the procedure intentionally overestimates risks to “*ensure that potential ecological threats are not overlooked*” (EPA, 1997). However, the HQ method does limit the information because it provides only a single point of comparison for the exposure-response relationship.

Given the use of conservative assumptions regarding exposure and potential toxicological effects, there is minimal uncertainty that the potential ecological risks from seep-related COPECs went undetected in the ERA process. Conversely, there is the probability for a false positive (that is, overestimating risk and concluding that there are ecological risks for benthic invertebrates).

9.3 Future Exposure Scenarios

The SLERA evaluated potential ecological exposure using the most recent data collected for relevant exposure pathways. In letters dated November, 18, 2014 and December 7, 2015 (in error), EPA requested a qualitative discussion of future possible land use scenarios with no man-made controls on the Salem Canal, including Munson Dam and the average potable water intake of approximately 9.5 mgd. EPA also requested consideration of the potential effects of future climate change on the Salem Canal. These future considerations are evaluated below as uncertainties regarding the SLERA conclusions.

Current land use of Chambers Works as an industrial facility is expected to remain the same in the future. Therefore, there is a low probability that future land use scenarios would not include the operation of Munson Dam and the potable water intake, which are critical to the on-going operation of Chambers Works. Munson Dam, working in conjunction with Brown Dam located about 2 miles to the east on the Salem River main stem downstream of the canal confluence, provides and maintains a supply of freshwater to Chambers Works by blocking the tidal influx of brackish Delaware River water and impounding freshwater from the upper Salem River to the canal. Water levels in the canal are maintained by freshwater releases at Munson Dam, as well as pumping wells operated by Chemours. Both Munson Dam and Brown Dam act as barriers to tidal waters from the Delaware River. The freshwater supply provided by Munson Dam and Brown Dam is critical not only to the Chambers Works facility, but also to the miles of agricultural land use upstream of Chambers Works in the Salem River. Given this critical need for a freshwater supply, there is a low probability that the Munson Dam would be removed.

The unlikely removal of the Munson Dam (without the removal of Brown Dam) would modify the hydrodynamics of Salem Canal and the Salem River upstream of Chambers Works. With the reintroduction of tidal cycles, the flow regime of the canal would change from an impoundment with low flow velocities and a maintained water level to a twice-daily flushed system experiencing bi-directional flows and twice-daily water level fluctuations of approximately 5 to 6 feet. The present impounded hydrologic regime promotes sedimentation at an estimated linear accumulation rate of 1.3 to 1.6 cm/year

(see Section 3.1). In contrast, a tidal regime would introduce increased flow velocities and shear stresses likely capable of eroding the canal bottom and, where unprotected, canal banks. If unprotected, the Former Seep Area may experience erosion with the potential for dispersion of impacted sediment. The introduced tidal regime would likely extend upstream in the Salem River to Brown Dam and upstream where freshwater habitats will be impacted by brackish water and tidal hydrology. The influx of brackish water and tidal hydrology to these upstream areas would dramatically alter the freshwater ecological resources that currently exist in the Salem Canal for miles upstream of the site.

The uncertainty of future land use scenarios on ecological exposure in the Salem Canal would be re-evaluated in the highly improbable event of the removal of the Munson Dam. Any potential breach or removal of the dam would require significant regulatory oversight, permits, and public notice. Potential implications of the dam removal on seep-impacted sediments of the Salem Canal would be considered as part of a feasibility evaluation of removing the dam. However, the potential future impacts associated with the Former Seep Area are relatively minor in the context of the widespread ecological impacts on freshwater habitats in the Salem Canal and Salem River that would result from the influx of tidal brackish water.

The potential effects of climate change on the Salem Canal also represent an uncertainty. The potential effects of broad climate change are not fully understood, including the potential changes in local hydrology that may result from climate change. With changing climatic conditions, water flow within streams and rivers may vary widely due to droughts or flooding. Other changes that may occur include increased water temperature, increased nutrient loading, and changes in biota living in and along these water bodies. For the Salem Canal, the level of uncertainty associated with climate change is relatively low due to the control of water levels by Munson Dam and groundwater wells operated by the Chambers Works Facility. During severe drought, Chemours has the capability of supplementing the Salem River and Canal with freshwater several miles upstream of the facility via pumping wells. In flooding situations, water is released from the Munson Dam into the Delaware River to maintain the water level within the canal. Water management controls are therefore in place to minimize extreme conditions that may result from climate change.

9.4 Summary

In general, conservative estimates or assumptions were made for most parameters associated with ecological exposures and effects in the screening-level and refined exposure evaluations. Therefore, confidence is high that the conclusions regarding the potential for adverse ecological harm are adequately conservative to quantify potential risks to ecological receptors.

10.0 Conclusions and Recommendations

The purpose of this Revised SLERA is to evaluate potential risks to ecological receptors exposed to site-related constituents under current conditions in the Salem Canal adjacent to Chambers Works. Potential ecological exposure was evaluated using screening-level exposure estimates that quantified potential risk based on the most conservative exposure scenario and refined exposure estimates that quantified potential risk based on more representative, yet protective exposure scenarios. Conclusions and recommendations for the Canal-Wide Area and Former Seep Area are presented below.

10.1 Canal-Wide Area

The characterization of ecological risk in the Canal-Wide Area indicated limited, localized potential for adverse effects to the benthic invertebrate community and negligible potential for adverse effects to fish and semi-aquatic wildlife potentially foraging throughout the Salem Canal. Potential exposure to benthic invertebrate communities within the Canal-Wide Area included evaluation of exposure within Reach 1, Reach 2 (outside of the Former Seep Area), and the Tidal Reach; potential exposure to fish and semi-aquatic wildlife receptors were evaluated based on combined data from the Canal-Wide Area and Former Seep Area. The results of the refined exposure evaluation indicated that the potential for adverse effects within the Canal-Wide reaches was limited to benthic invertebrates in localized areas adjacent to outfalls. Sediment characterization sampling in 2018 further defined the limited spatial extent of elevated concentrations adjacent to these outfalls. Given that exposure was localized at select sampling stations adjacent to outfalls, community-level effects to the broader benthic invertebrate community within the Canal-Wide Area are not likely.

Consistent with previous investigations, surface water quality in the Salem Canal was not adversely impacted by site-related constituents; therefore, the potential for adverse effects to the fish community resulting from direct contact exposure is negligible. An evaluation of dietary exposure to fish based on estimated dietary concentrations and dietary endpoints for fish survival, growth, and reproduction indicate minimal potential for adverse effects.

Potential exposures to semi-aquatic wildlife via ingestion pathways in the Salem Canal are not unacceptable based on modeled dietary doses below TRVs and the limited opportunity for exposure due to a lack of available habitat. Based on these findings for the Canal-Wide Area, no unacceptable risks were identified for ecological receptors. Therefore, no further investigation or monitoring of the Canal-Wide Area is warranted based on ecological risk.

10.2 Former Seep Area

The characterization of ecological risk in the Former Seep Area indicated limited potential for adverse effects to the benthic invertebrate community. Given the limited size of the Former Seep Area, the survival, growth, and reproduction of the benthic community was the only assessment endpoint identified for this exposure area; exposures to fish and semi-aquatic wildlife that may forage a portion of the time in the Former Seep Area were evaluated as part of the exposure evaluation for the broader Canal-Wide Area. Evaluation of current exposure to the benthic community within the Former Seep Area based on bulk sediment and pore water data collected in 2015-2016 indicate that the potential for adverse ecological effects is limited. Significant reductions

in seep-related constituent concentrations in bulk sediment have reduced overall exposure in 2015 relative to the previous evaluation in 2011. However, continued monitoring of exposure conditions within the BAZ will be conducted in 2020 to further support the weight-of-evidence evaluation of natural recovery in sediment within the Former Seep Area following the installation of the SPB.

Ecological exposure conditions in the BAZ within the Former Seep Area are conducive to natural recovery because the potential for adverse effects during the recovery period is limited, if present, in sediment. The limited potential for short-term adverse ecological effects is based on the following exposure conditions specific to the Salem Canal, as supported by the Revised SLERA conclusions:

- Relevant exposure pathways for sediment are limited to direct contact toxicity to benthic invertebrate receptors resulting in localized areas of potential impacts.
- Seep-related COPECs have a limited potential to bioaccumulate or bioconcentrate; therefore, as demonstrated with dose rate models in the SLERA, exposure pathways to semi-aquatic wildlife receptors are not significant.
- Pore water evaluations indicate that seep-related constituents are not bioavailable at concentrations that are likely to result in direct contact toxicity to benthic invertebrate receptors.
- Bulk sediment evaluations indicate spatially-limited exceedances of benchmark concentrations that conservatively estimate the bioavailability and partitioning of seep-related constituents to pore water.
- No impacts to surface water quality from seep-related constituents in sediment were observed in multiple sampling events.

Given the limited ecological exposure in the Former Seep Area under current conditions and the potential for the degradation of seep-related constituents over time, the MNR Framework was submitted to EPA and NJDEP (URS, 2015). Specific recommendations for future monitoring within the Former Seep Area were presented in the *2017 Salem Canal Investigation Summary Report* (AECOM and EHS Support, 2017). An additional monitoring event will be conducted in 2020 consistent with the MNR Framework to assess natural recovery processes in sediment and further support the ECSM to ensure that conditions within the Former Seep Area of the Salem Canal remain protective of the environment.

NJDEP SRP PI# 008221
EPA I.D. Number: NJD 002385730

Dear Mr. Hartten:

The United States Environmental Protection Agency (EPA) Region 2 and The New Jersey Department of Environmental Protection (NJDEP) have completed review of the Revised Salem Canal Screening Level Ecological Risk Assessment (SLERA) Report dated April 12, 2017, submitted pursuant to the Resource Conservation and Recovery Act (RCRA) Hazardous and Solid Waste Amendments (HSWA) Permit and the Technical Requirements for Site Remediation at N.J.A.C. 7:26E (Tech Regs). EPA comments are below. Also, enclosed please find the review comments provided by the NJDEP.

General Comments

USEPA's Ecological Risk Assessment Guidance for Superfund (ERAGS) does not contain a "Step 3A." Section 3.2 of ERAGS states that the risk assessor should "consider how the HQs would change if more realistic conservative assumptions were used instead." This reevaluation involves using more realistic assumptions about exposures and a comparison of these revised exposure estimates (mean and/or 95% UCL concentrations) with ESVs and TRVs. This step also allows for the use of background, frequency and magnitude of detection, and dietary considerations to be used to reduce the list of COPECs.

Fish were evaluated as a receptor of concern solely based on their “continuous contact with surface water.” The report states that “demersal fish may also be exposed to COPECs through the direct ingestion of sediment-associated prey and the incidental ingestion of sediment and pore water while foraging in sediment” however these exposure pathways were not quantified. It seems more likely that fish are present in the canal than are the semi-aquatic wildlife evaluated based on habitat conditions. Demersal fish exposure should have been evaluated and quantitated in this Revised SLERA using conservative food-chain models.

Section 5.1.2 states that sediment data for perfluorinated compounds were not included in the SLERA and will be included a separate submittal containing the Chambers Works perfluorinated compound conceptual model. Information should be presented here to explain why this separate submittal was prepared and how it may impact on this Revised SLERA.

The summary tables of COPECs presented on pages 31 and 34 – 35 need to be checked carefully against the data in Tables 7 through 20. The following inconsistencies are noted (there may be more):

- According to Table 7, carbozole and o-toluidine have maximum concentrations greater than ESVs and should be included as COPECs for the 0 – 0.5 foot depth of bulk sediment.
- According to Table 9, 2-methylphenol does not have an ESV and should not be included in the pore water 0 – 0.5 foot depth.
- Table 15 shows bis(2-ethyl)hexylphthalate greater than the ESV for the Reach 1, 0 – 0.5 foot depth but it is not included on page 35.
- Cobalt is not a COPEC for Reach 1, 0 – 0.5 foot depth in Table 15.
- Table 16 shows carbozole as a COPEC for Reach 1, 0.5 – 1.0 foot depth bulk sediment but it is not on page 35.
- Table 18 shows carbozole as a COPEC for Reach 2, 0.5 – 1.0 foot depth bulk sediment but it is not on page 35.
- Table 19 shows 4-methylphenol (p-cresol), 4,4-DDE, and endosulfan 1 as COPECs for Tidal Reach 0 – 0.5 foot depth bulk sediment but they are not on Tables in Section 6.2.1.
- 4-methylphenol (p-cresol) and total PCBs are COPECs on Table 20 (Tidal Reach 0.5 – 1 foot depth bulk sediment but are not on Tables in Section 6.2.1.

The recommendation of Monitored Natural Recovery in the Former Seep Area may not be needed if sediment removal in certain areas of the Salem Canal occur.

Specific Comments

1. Page 10, Section 4.2.2, last sentence should read "Groundwater discharge ... along most of the shoreline of the Salem Canal **Study Area** has effectively"
2. Page 20, Section 4.7, 3rd paragraph, last sentence – Pore water is one item in a weight of evidence approach and is not "afforded greater weight in estimating exposure and characterizing risk to benthic invertebrates." As stated to Chemours previously, more effective methods to evaluate exposure are toxicity testing, tissue sampling, and bioaccumulation studies.
3. Page 38, first partial sentence – The maximum HQ of these three COPECs is 10.5 as shown on Table 17.
4. Page 38, 2nd paragraph, 3rd sentence – Maximum HQs for these three COPECs range from 3.4 to 9.6.
5. Page 39, 2nd full paragraph – There is no discussion of 4-methylphenol (p-cresol) greater than ESVs.
6. Page 45, Section 7.2.3 – Frequency of detection can be used to exclude COPECs from evaluation in the BERA but as stated on page 3 of the June 2001 ECO Update (EPA 540/F-01/014) "it is essential to evaluate bioaccumulation, bio-magnification, and bio-concentration of each such contaminant as well."

Upon your receipt and review of the comments, we would recommend a conference call to address any questions and discuss a path forward. Please submit a written response addressing the enclosed comments no later than sixty (60) days from the date of your receipt of this letter.

To set up a call or if you have any questions, please call Helen Dudar, of NJDEP, at (609) 633-9279, or Sam Abdellatif, of my staff, at (212) 637-4103.

Sincerely yours,

Ben Conetta, Chief

Re: Chemours' Revised Salem Canal Screening – Level Ecological Risk Assessment, April 12, 2017
Chemours Chambers Works
Route 130
Deepwater, Salem County
SRP PI # 008221

Dear Mr. Abdellatif:

The New Jersey Department of Environmental Protection (Department, NJDEP) has completed review of the Revised Salem Canal Screening – Level Ecological Risk Assessment (SLERA). This document was reviewed in accordance with the Technical Requirements for Site Remediation (N.J.A.C. 7:26E), the Ecological Evaluation Technical Guidance (NJDEP 2015) found at http://www.nj.gov/dep/srp/guidance/srra/ecological_evaluation.pdf (EETG), NJDEP policy, and applicable federal regulations.

Below are the Department's comments.

Technical Coordinator Comments

1. **5.1.1 Former Seep Area – Pore Water:** The SLERA states that the "0.5 to 0.75-foot and 0.75 to 1.0-foot intervals conservatively evaluate exposure in the sampling interval immediately below the biologically active zone (BAZ), consistent with NJDEP (2015)."

Section 5.3.3.1 Soil and Sediment of NJDEP 2015 indicate samples are to be collected from the zero to six inch and six to twelve inch intervals and other six inch intervals as appropriate.

Section 6.2.2.3 Pore Water Sampling and Appendix F - Sediment Pore Water Sampling Techniques of this SLERA do not indicate sampling intervals.

Therefore, consistent with NJDEP 2015, samples should be collected at six inch intervals unless justification (i.e. change in sediment type) is provided to sample at different interval thickness. Please address this issue.

2. **5.2.2 Wildlife Ingestion Pathway Evaluation:** The SLERA uses a “Low TRV” and a “High TRV;” however, instead of using a NOAEL and LOAEL for the “Low TRV” and “High TRV,” the SLERA uses two different NOAELs.

Consistent with Section 6.1.3.3 Toxicity Reference Values (TRVs) of NJDEP 2015, the hazard quotient (HQ) range should be bounded by a NOAEL and a LOAEL. NJDEP has a draft TRV Policy which will be incorporated into the next revision of NJDEP 2015. A portion of that policy is attached. More detailed comments regarding TRVs are found in Department comments on Appendix D Wildlife Exposure Modeling Documentation, below. Please address this issue.

3. **7.2.3 Frequency of Detection:** The SLERA states that “COPECs with detection frequencies of less than 5 percent were not evaluated further.” The magnitude of the exceedance and distribution of detections must also be taken into account prior to eliminating a COPEC from consideration at a site, consistent with Section 5.5 Ecological Evaluation Report of NJDEP 2015. Please address this issue.
4. **7.2.4 Comparison to Background Threshold Values:** The SLERA states that “maximum and refined exposure point concentrations (EPCs) were compared to background threshold values (BTVs) to evaluate site data in the context of regional conditions.” When comparing site data to background data, like statistics must be compared (i.e., maximum to maximum, average to average, etc.). Please address this issue.
5. **8.2.2 Refined Risk Characterization and SMDP – Scientific Management Decision Point:** The SLERA states that “there is no need for remediation based on ecological risk”.

However, isolated hot spots do exist and should be evaluated in accordance with Section 6.4.4 Hot Spots of NJDEP 2015. Please address this issue.

6. **Figures 17 and 22:** These figures indicate elevated levels of mercury (3.36 mg/kg and 1.86 mg/kg) adjacent to Outfall Q.

In accordance with Section 6.0 Technical Guidance for Preparing Ecological Risk Assessments of NJDEP 2015, “treatment and removal should be considered for sites where ecological risk is determined to be negligible if persistent, biomagnifying, toxic [contaminants] are present.” Please address this issue.

7. **Figures 18 and 23:** These figures indicate elevated levels of mercury (2.41 mg/kg and 2.92 mg/kg adjacent to Outfall M; 1.45 mg/kg adjacent to Outfall H; 2.44 mg/kg adjacent to Outfall F; 1.77 mg/kg adjacent to Outfall E; and 1.83 mg/kg and 5 mg/kg adjacent to Outfall D) as well as PAHs (9.78 mg/kg and 11.295 mg/kg adjacent to Outfall M).

In accordance with Section 6.0 Technical Guidance for Preparing Ecological Risk Assessments of NJDEP 2015, “treatment and removal should be considered for sites where ecological risk is determined to be negligible if persistent, biomagnifying, toxic [contaminants] are present.” Please address this issue.

8. **Figures 19 and 24:** These figures indicate elevated levels of metals (1,210 mg/kg lead and 45.8 mg/kg arsenic adjacent to Outfall 013) as well as PAHs (22.907 mg/kg and 13.792 mg/kg adjacent to Outfall 011). In accordance with Section 6.0 Technical Guidance for Preparing Ecological Risk Assessments of NJDEP 2015, “treatment and removal should be considered for sites where ecological risk is determined to be negligible if persistent, biomagnifying, toxic [contaminants] are present.” Please address this issue.

9. **Appendix D – Wildlife Exposure Modeling Documentation:**

1.0 Introduction: The text states that “the Salem Canal provides limited wildlife habitat due to the lack of riparian vegetation and cover along the developed shoreline of the facility.” Whereas this is correct, the southern shore of the Salem Canal is largely vegetated adjacent to the facility and provides some habitat.

2.3 Toxicity Reference Values: As stated in 5.2.2 Wildlife Ingestion Pathway Evaluation, above, the SLERA uses a “Low TRV” and a “High TRV;” however, instead of using a NOAEL and LOAEL for the “Low TRV” and “High TRV,” the SLERA uses two different NOAELs. Consistent with Section 6.1.3.3 Toxicity Reference Values, the HQ range should be bounded by a NOAEL and a LOAEL. NJDEP has a draft TRV Policy which will be incorporated into the next revision of NJDEP 2015. A portion of that policy is attached. Please address this issue.

Table D1: The home range for the Great Blue Heron is listed as 7-8 km (15,000-20,000 ha). Whereas this is correct, it is the foraging distance from the colony and the size of the Feeding Territory is 0.6 (fall) to 8.4 (winter) ha. When calculating an area use factor (AUF), the feeding territory should be used instead of the home range (foraging distance from colony) since the Great Blue Heron may travel a greater distance to a food source, but feed in a smaller area, once at a suitable feeding area. Given that an AUF of 1 was used in this document, it does not impact the calculations, but should be used if an AUF is considered in the future. Please address this issue.

Table D4: Using the NJDEP TRV policy, some examples of differences in TRVs are as follows:

Analyte	Chambers Works Avian Low TRV	NJDEP Avian Low TRV (NOAEL)	Chambers Works Avian High TRV	NJDEP Avian High TRV (LOAEL)	Chambers Works Mammalian Low TRV	NJDEP Mammalian Low TRV (NOAEL)	Chambers Works Mammalian High TRV	NJDEP Mammalian High TRV (LOAEL)
Copper	18.4	2.3	34.8	4.7	25	3.4	82.7	6.8
Lead	10.9	0.19	44.6	1.9	40.7	0.71	182.4	7.0
Mercury	0.45	0.013	0.91	0.026	1	0.016	NA	0.027
Total LMW PAHs	16.1	0.67	161	6.7	65.6	50	170	150
Total HMW PAHs	2	0.048	20	0.48	0.615	0.62	18	3.1
Total DDx	0.009	0.009	1.5	0.027	0.8	0.8	4	4
Dieldrin	0.077	0.054	0.77	0.18	0.02	0.015	0.2	0.030
Total PCB	0.09	0.4	1.27	0.5	0.36	0.069	1.28	0.082

Whereas some of the NJDEP TRVs are higher than the Chambers Works TRVs, many are lower, sometimes by an order of magnitude. The choice of TRVs has a large impact on the risk calculation. Risk should be recalculated based on appropriate NOAELs and LOAELs in accordance with the NJDEP draft policy. Please address this issue.

10. Appendix E – Sediment Quality Benchmark (SQB) Documentation:

2.0 Derivation of Sediment Quality Benchmarks: Thirteen of the twenty-seven COPECs listed as being derived for the SLERA have NJDEP ecological screening criteria (ESC). Whereas an RP may propose alternate ESC, justification must be provided for the alternate ESC. Chambers Works should provide justification for using each of the alternate ESC. Please address this issue.

Table E1: Two of the six COPECs listed as being derived for the SLERA have NJDEP ESC. Whereas an RP may propose alternate ESC, justification must be provided for the alternate ESC. Chambers Works should provide justification for using each of the alternate ESC. Please address this issue.

Selection of Toxicity Reference Values (draft policy)

The approach provided below is consistent with USEPA as mandated by the *Brownfield and Contaminated Site Remediation Act* by “use of the guidance and regulations for exposure assessment developed by the United States Environmental Protection Agency pursuant to the ‘Comprehensive Environmental Response, Compensation, and Liability Act of 1980,’ 42 U.S.C. § 9601 et seq. and other statutory authorities as applicable” and provides the user with a framework from which to develop TRVs; however, as with all guidance documents issued by the NJDEP, the person conducting the remediation may deviate from this approach and propose an alternate TRV based on site-specific circumstances provided that adequate justification is provided. The process to request a variance is outlined in NJAC 7:26E 1.7 and Section 1.0 Intended Use of Guidance Document.

The first tier of TRVs to consider are those used in the *Focused Feasibility Report for the Lower Eight Miles of the Lower Passaic River* (USEPA 2014), Appendix D. These TRVs were vetted by NJDEP, USEPA, USFWS, NOAA, have been used in support of the Record of Decision (ROD) for the Passaic River Lower Eight Mile Superfund site, are considered sufficiently conservative, and will not be subject to further scrutiny during SRWMP’s inspection and review process. Table 1 provides the list of TRVs from the *Focused Feasibility Study Report for the Lower Eight Miles of the Lower Passaic River, (2014)* – Table 4-14, available at (<http://passaic.sharepointspace.com/Public%20Documents/2014-02-20%20Appendix%20D%20Risk%20Assessment.pdf>).

The second tier of TRVs are USEPA’s Ecological Soil Screening Levels (Eco-SSLs, USEPA, 2005a et seqq.) and are recommended for contaminants not included on Table 1. When using TRVs from the contaminant-specific Eco-SSL documents, the NOAEL- and LOAEL-based TRVs should be those used by USEPA for the derivation of Eco-SSLs. The Eco-SSLs are most typically the highest bounded NOAEL that is lower than the lowest bounded LOAEL for reproduction, growth and/or mortality (“bounded” means a study from which a NOAEL-LOAEL pair was determined). However, for certain contaminants, Eco-SSLs may have been derived from the geometric mean of NOAELs for growth and reproductive effects from vetted studies; in that case, an appropriately conservative LOAEL should be selected. If TRVs other than these were used by USEPA to develop the Eco-SSLs, then those TRVs should be used.

The third tier of TRVs are taken from literature sources. Caution should be used to be sure these literature sources were not reviewed and rejected by USEPA during derivation of the Eco-SSLs. Appropriate justification should be provided for use of a particular literature source and for the TRVs chosen from that literature source. Justification can include the type of study, receptor used and dosing methodologies, as well as other factors. Notwithstanding the use of statistical evaluations in USEPA 2005, it is recommended that third-tier TRVs be developed from a single study or receptor with bounded NOAELs and LOAELs and should not be based on statistical evaluations of multiple TRVs/studies across several receptors, as errors and uncertainty can be introduced into the calculations; moreover, it is expected that this third tier will be used for less common contaminants, with potentially too few studies available for statistical evaluations.

If TRVs are used to determine ecological risk-based remediation goals, they will be reviewed by NJDEP SRWMP in that context, because ecological remediation goals require Department pre-approval (N.J.A.C. 7:26E-4.8(c) 3).

Table 1 – Summary of TRVs for Avian and Mammalian Wildlife Receptors from the Passaic River FFS

COPEC	TRV ^a		Species	Common Name	Endpoint	Reference
	NOAEL	LOAEL				
<i>Birds</i>						
Copper	2.3	4.7	<i>Melagris gallopavo</i>	Domesticated Turkey	growth	Kashani et al., 1986

2,3,7,8-TCDD	8.0E-08	2.2E-06	<i>Neovison vison</i>	American Mink	reproduction	Tillitt et al., 1996

(a) Units are µg COPEC/g BW-day (dry weight basis).

(b) Benchmarks based on methylmercury exposure.

Additional comments by Ecological Risk Assessor

The report was reviewed the above-referenced SLERA in accordance with the Technical Requirements for Site Remediation (N.J.A.C. 7:26E), the Ecological Evaluation Technical Guidance (EETG) and NJDEP policy. The following comments are based on a review from an ecological perspective.

Comments

This reviewer has no comments to add to the Technical Coordinator's comments above.

However, the following comments from review of the February 2017 *Salem Canal Investigation Report* are worth reiterating as they support the Department's disagreement with Chemours Revised SLERA conclusions that no further ecological investigation or monitoring of the Canal-Wide Area is warranted and that future monitoring of the "potential for the degradation of seep-related constituents over time" within the Former Seep Area (as presented in the AECOM and EHS Support, 2017 *Salem Canal Investigation Summary Report* and the URS 2015 *MNR Framework*) is all that is required in the Former Seep Area. Please address this issue and the supporting issues listed below.

1. Sediment sample SC-236-OutT2 (0.5-1.0), collected in the Tidal Reach, contains 118 ppm total PCBs. This high level appears to be a site-related constituent and needs to be delineated and addressed.
2. Reach 2 sediment sample SC-189OutF9 (1.0'-2.5') contains the highest concentration of PFAs detected in the Salem Canal. The levels are much higher than those detected in the Reference Area of the canal and appear to be site-related. No sediment benchmark was provided; however, the extent of elevated levels of PFAs in canal sediments remains undelineated. This issue should not be bifurcated from the SLERA.

3. If monitoring of the former Seep Area is the future course of action, it is recommended that bulk sediment monitoring sampling events be conducted more frequently than every 4 years as previously proposed by Chemours.
4. Levels of several inorganics detected in Tidal Reach and Reach 2 sediment samples exceed their Severe Effects Level Ecological Screening Criteria (ESLs) and background UTLs (i.e., chromium, copper, lead, and mercury). These elevated levels need to be addressed.
5. Sediment and surface water quality and associated ecological exposure in the Tidal Reach are influenced by both the Salem Canal and the Delaware River. Ecological data from the Tidal Reach are just as appropriately evaluated with data from the Salem Canal as they are with data from the Delaware River (Pertains to comments #1 and #4 above). Sediment or surface water impacts from historic or active outfalls should not be casually attributed to contaminant tidal influx from the Delaware River. In fact, the opposite cannot be ruled out.

If you have any questions, please contact me at 609-292-3007.

**RE: Revised Salem Canal Screening-Level Ecological Risk Assessment
Chemours Chambers Works, Route 130
Deepwater, Salem County, New Jersey
NJDEP SRP PI# 008221
EPA I.D. Number: NJD 002385730**

Dear Mr. Conetta:

The attached matrix presents responses to comments received from the United States Environmental Protection Agency (EPA) and New Jersey Department of Environmental Protection (NJDEP) on the Revised Screening-Level Ecological Risk Assessment (Revised SLERA) that was completed for the Salem Canal adjacent to The Chemours Company (Chemours) Chambers Work facility in Deepwater, New Jersey. The SLERA was submitted to EPA and NJDEP on April 12, 2017 pursuant to the Resource Conservation and Recovery Act (RCRA) Hazardous and Solid Waste Amendments (HSWA) and the Technical Requirements for Site Remediation (N.J.A.C. 7:26E). EPA and NJDEP comments were received on November 28, 2017, in a letter dated November 24, 2017.

Responses to some EPA and NJDEP comments on the Revised SLERA address similar comments provided by EPA and NJDEP in the September 24, 2017 comment letter on the *2017 Salem Canal Investigation Summary Report*. In the December 7, 2017 letter responding to comments on the *2017 Salem Canal Investigation Summary Report*, Chemours deferred responses to several ecological risk-related comments pending the review of EPA and NJDEP comments on the Revised SLERA. The deferred responses to comments on the *2017 Salem Canal Investigation Summary Report* are provided in the attached responses to similar comments on the Revised SLERA.

Responses to EPA and NJDEP comments on the Revised SLERA are presented in the attached matrix; the text of the comments provided in the EPA and NJDEP letter is presented in the left column and the associated Chemours response is provided in the adjacent column to the right of each comment.

Following your review of the responses, Chemours welcomes the opportunity to discuss and resolve any outstanding comments that you may have, and to determine the next appropriate steps.

If you have any further questions, please email me at Andrew.S.Hartten@chemours.com or call me at 302.773.1289.

Respectfully,

Andrew H. Hartten
Project Director, Chambers Works
The Chemours Company

Responses to EPA/NJDEP Comments on the Revised Salem Canal Screening-Level Ecological Risk Assessment (11/24/17)
Chemours Chambers Works, Route 130
Deepwater, Salem County, New Jersey
NJDEP SRP PI# 008221
EPA I.D. Number: NJD 002385730

EPA/NJDEP Comment	Chemours Response
EPA General Comments	
<p>1 USEPA's Ecological Risk Assessment Guidance for Superfund (ERAGS) does not contain a "Step 3A." Section 3.2 of ERAGS states that the risk assessor should "consider how the HQs would change if more realistic conservative assumptions were used instead." This reevaluation involves using more realistic assumptions about exposures and a comparison of these revised exposure estimates (mean and/or 95% UCL concentrations) with ESVs and TRVs. This step also allows for the use of background, frequency and magnitude of detection, and dietary considerations to be used to reduce the list of COPECs.</p>	<p>The analyses presented in the Refined Ecological Exposure Evaluation (Section 7.0) and corresponding Refined Exposure Estimate and Risk Characterization (Section 8.0) were consistent with the re-evaluation procedures prescribed in ERAGS Section 3.2 and identified in the EPA comment. References to ERAGS Step 3A will be replaced in the <i>Revised Salem Canal Screening Level Ecological Risk Assessment (Revised SLERA)</i> with references to ERAGS Section 3.2.</p> <p>It is important to note that while ERAGS does not specifically identify Step 3A, supplemental federal guidance on ecological risk assessment identifies Step 3A as an important step to refine and focus the ecological risk assessment process (EPA, 2015; TSERAWG, 2008; EPA, 2000; U.S. Navy, 1999). In practice, Step 3A refinements have been included in the ecological risk assessment process at multiple sites (e.g., ARCADIS, 2015; AECOM, 2013; EPA, 2003).</p>
<p>2 Fish were evaluated as a receptor of concern solely based on their "continuous contact with surface water." The report states that "demersal fish may also be exposed to COPECs through the direct ingestion of sediment-associated prey and the incidental ingestion of sediment and pore water while foraging in sediment" however these exposure pathways were not quantified. It seems more likely that fish are present in the canal than are the semi-aquatic wildlife evaluated based on habitat conditions. Demersal fish exposure should have been evaluated and quantitated in this Revised SLERA using conservative food-chain models.</p>	<p>As indicated in the July 10, 2015 response to EPA comments regarding the potential evaluation of dietary exposure to fish, it was discussed and agreed to during a June 23, 2015 teleconference between EPA, NJDEP, and Chemours that the ecological conceptual site model (ECSM) would be revised to include potentially complete pathways for demersal fish, including the direct ingestion of sediment-associated biota and direct contact with bulk sediment and pore water. However, it was also stated in the response that the revised ECSM would distinguish between primary pathways that would be quantitatively evaluated in the SLERA and secondary pathways that may be complete, but are not quantitatively evaluated. Dietary exposure pathways for demersal fish were identified as potentially complete, but not quantitatively evaluated in the Revised SLERA.</p> <p>To address EPA's concerns regarding potential exposure to demersal fish, a literature review will be conducted to evaluate the availability of information to support a quantitative assessment of dietary exposure pathways to fish. Contingent upon the availability of information to support exposure assumptions and derive COPEC-specific toxicity reference values (TRVs), dietary exposure pathways for demersal fish will be evaluated for COPECs with the potential to bioaccumulate (as identified for wildlife ingestion pathways in Section 5.2 of the Revised SLERA). For COPECs with sufficient information to derive COPEC-specific TRVs, dietary exposure to demersal fish will be estimated based on the direct ingestion of sediment-associated prey (i.e., benthic invertebrates) and the incidental ingestion of sediment. If TRVs cannot be identified or derived for a given COPEC, estimated dietary concentrations in sediment-associated prey in the Salem Canal will be directly compared to dietary concentration endpoints [e.g., no observed effect concentrations (NOECs) or low observed effect concentrations (LOECs)] from available toxicological databases (e.g., ECOTOX) or literature sources, as available. The identification of exposure parameters, the derivation of TRVs, and the selection of dietary concentration endpoints will be documented in Appendix D (Wildlife Exposure Modeling Documentation) of the Revised SLERA.</p>

Responses to EPA/NJDEP Comments on the Revised Salem Canal Screening-Level Ecological Risk Assessment (11/24/17)
Chemours Chambers Works, Route 130
Deepwater, Salem County, New Jersey
NJDEP SRP PI# 008221
EPA I.D. Number: NJD 002385730

EPA/NJDEP Comment		Chemours Response
3	Section 5.1.2 states that sediment data for perfluorinated compounds were not included in the SLERA and will be included a separate submittal containing the Chambers Works perfluorinated compound conceptual model. Information should be presented here to explain why this separate submittal was prepared and how it may impact on this Revised SLERA.	Perfluoroalkyl substances (PFAS) compounds were not included in the Revised SLERA due to the limited availability and uncertainty associated with ecotoxicity data to evaluate ecological exposure to PFAS. A discussion of the PFAS analytical results for sediment and surface water samples collected within the Salem Canal was presented in Appendix B7 of the <i>2017 Salem Canal Investigation Summary Report</i> . PFAS data from the Salem Canal were also incorporated into the <i>Conceptual Site Model (CSM) for Poly- and Perfluoroalkyl Substances</i> submitted to EPA and NJDEP in July 2017. The CSM document placed the occurrence of PFAS in sediment and surface water samples from the Salem Canal in the broader spatial and temporal context of the Chambers Works Complex. Given that ecological exposure to PFAS could not be evaluated due to limited and uncertain ecotoxicity data and that PFAS occurrence and distribution in within the Salem Canal were presented in other site documents, these data were not included in the Revised SLERA. Further clarification of the documentation of PFAS data collected in sediment and surface water within the Salem Canal will be provided in the Revised SLERA.
4	The summary tables of COPECs presented on pages 31 and 34 - 35 need to be checked carefully against the data in Tables 7 through 20.	COPEC summary tables in the Revised SLERA will be carefully re-checked and revised as necessary.
5	The recommendation of Monitored Natural Recovery in the Former Seep Area may not be needed if sediment removal in certain areas of the Salem Canal occur.	Comment noted.
EPA Specific Comments		
1	Page 10, Section 4.2.2, last sentence should read " Groundwater discharge . . . along most of the shoreline of the Salem Canal Study Area has effectively	The text will be revised to add the phrase "Study Area" as requested.
2	Page 20, Section 4.7, 3rd paragraph , last sentence - Pore water is one item in a weight of evidence approach and is not "afforded greater weight in estimating exposure and characterizing risk to benthic invertebrates." As stated to Chemours previously, more effective methods to evaluate exposure are toxicity testing, tissue sampling, and bioaccumulation studies.	The statement about affording greater weight to pore water results in the weight-of-evidence evaluation of risk to benthic invertebrates was intended to discuss the relative weight of measurement endpoints evaluated in the Revised SLERA. Based on the measurement endpoints evaluated in the Revised SLERA, pore water is a more reliable predictor than bulk sediment comparisons to ESCs or theoretical equilibrium partitioning (EqP) sediment benchmarks. This statement will be clarified in the Revised SLERA.
3	Page 38, first partial sentence - The maximum HQ of these three COPECs is 10.5 as shown on Table 17.	The text will be updated in the Revised SLERA to reflect an HQ of 10.5 (carbazole) as indicated in the comment.
4	Page 39, 2nd full paragraph - There is no discussion of 4-methylphenol (p-cresol) greater than ESVs.	The text will be updated in the Revised SLERA to include a discussion of 4-methylphenol (p-cresol).

Responses to EPA/NJDEP Comments on the Revised Salem Canal Screening-Level Ecological Risk Assessment (11/24/17)

EPA/NJDEP Comment	Chemours Response
<p>5 Page 45, Section 7.2.3 - Frequency of detection can be used to exclude COPECs from evaluation in the BERA but as stated on page 3 of the June 2001 ECO Update (EPA 540/F-01/014) "it is essential to evaluate bioaccumulation, bio-magnification, and bio-concentration of each such contaminant as well."</p>	<p>The "bioaccumulation, bio-magnification, and bio-concentration" potential of COPECs excluded based on low detection frequencies (less than 5 percent of samples) during the Refined Ecological Exposure Evaluation (see Section 7.0) was evaluated in the Revised SLERA. Five organic constituents were excluded as COPECs in bulk sediment or pore water based on low detection frequencies during COPEC refinement: 2-chlorophenol, bis(2-ethylhexyl)phthalate, o-toluidine, phenol, and carbazole. The "bioaccumulation, bio-magnification, and bio-concentration" potential of all five of these excluded organic constituents was evaluated as part of canal-wide dietary exposure modeling conducted during the Screening-Level Exposure Evaluation (see Section 5.2.2). Dietary exposure pathways were modeled in the Screening-Level Exposure Evaluation for potentially bioaccumulative organic COPECs, defined as constituents with log octanol-water partitioning coefficients (log Kow) greater than 3.5. Of the five COPECs excluded based on low detection frequencies, only bis(2-ethylhexyl)phthalate was potentially bioaccumulative (log Kow ≈ 8.4) and was included in the screening-level exposure models presented in Appendix D. The "bioaccumulation, bio-magnification, and bio-concentration" potential of the four remaining excluded COPECs was evaluated and considered to be low based on log Kow values less than 3.5.</p>
DEP Technical Coordinator Comments	
<p>1 5.1.1 Former Seep Area - Pore Water: The SLERA states that the "0.5 to 0.75-foot and 0.75 to 1.0-foot intervals conservatively evaluate exposure in the sampling interval immediately below the biologically active zone (BAZ), consistent with NJDEP (2015)."</p> <p>Section 5.3.3.1 Soil and Sediment of NJDEP 2015 indicate samples are to be collected from the zero to six inch and six to twelve inch intervals and other six inch intervals as appropriate.</p> <p>Section 6.2.2.3 Pore Water Sampling and Appendix F - Sediment Pore Water Sampling Techniques of this SLERA do not indicate sampling intervals.</p> <p>Therefore, consistent with NJDEP 2015, samples should be collected at six inch intervals unless justification (i.e. change in sediment type) is provided to sample at different interval thickness. Please address this issue.</p>	<p>The Revised SLERA will clarify the rationale and justification for the selection of sampling intervals and the use of bulk sediment and pore water data to support exposure estimates consistent with NJDEP Ecological Evaluation (EE) Technical Guidance (NJDEP, 2015).</p> <p>Bulk sediment and pore water data were collected to support exposure estimates in the Revised SLERA for vertical intervals that are consistent with or more stringent than NJDEP EE Technical Guidance (NJDEP, 2015). Section 5.3.3.1 of the EE Technical Guidance specifies that "<i>When COPECs are potentially present because of a subsurface discharge or groundwater migration pathway or the accretion of cleaner sediments over contaminated sediments may have occurred, samples should be collected from the point of discharge in soils or sediment and from both the zero to six and six to twelve-inch interval in sediments, respectively.</i>"</p> <p>Within the Former Seep Area, high-resolution sediment cores were collected to monitor bulk sediment concentrations over time in surface layers as prescribed in the <i>Bulk Sediment Sampling and Analysis Plan</i> submitted in March 2015. Four samples were collected within the 0-6-inch (in) interval within the Former Seep Area: 0-1 in, 1-2 in, 2-4 in, and 4-6 in. These data were used to estimate depth-weighted average concentrations for the 0-6-in interval. Below the 0-6-in interval, samples were collected in 6-in intervals to the maximum depth of sediment. Within the Canal-Wide Area, samples were collected from the 0-6-in and 6-12-in intervals and select intervals below 12 inches. This sampling design meets or exceeds the guidance in Section 5.3.3.1 of the EE Technical Guidance regarding the vertical resolution of bulk sampling to support an ecological evaluation for subsurface or surface discharges.</p> <p>Pore water was sampled within the Former Seep Area using high resolution peeper samples. Sampling ports within the peepers were spaced at 3-centimeter (cm; ~1.2-in) intervals. Depending on the station, 30-cm (approximately 12-in) or 90-cm (approximately 36-in) peepers were deployed with two sampling ports extending above the sediment-surface water interface. As stated in Section 5.1.1 of the Revised SLERA, pore water exposure was evaluated from sampling intervals relevant to benthic exposure: 0-6 in, 6-9 in, and 9-12 in. These exposure intervals were consistent with NJDEP EE Technical Guidance for sediment in the 0-6-in interval and provided greater resolution than the guidance requires for the 6-12 in interval.</p>

Responses to EPA/NJDEP Comments on the Revised Salem Canal Screening-Level Ecological Risk Assessment (11/24/17)
Chemours Chambers Works, Route 130

NJDEP SRP PI# 008221
EPA I.D. Number: NJD 002385730

	EPA/NJDEP Comment	Chemours Response
2	<p>5.2.2 Wildlife Ingestion Pathway Evaluation: The SLERA uses a "Low TRV" and a "High TRV;" however, instead of using a NOAEL and LOAEL for the "Low TRV" and "High TRV," the SLERA uses two different NOAELs.</p> <p>Consistent with Section 6.1.3.3 Toxicity Reference Values (TRVs) of NJDEP 2015, the hazard quotient (HQ) range should be bounded by a NOAEL and a LOAEL. NJDEP has a draft TRV Policy which will be incorporated into the next revision of NJDEP 2015. A portion of that policy is attached. More detailed comments regarding TRVs are found in Department comments on Appendix D Wildlife Exposure Modeling Documentation, below. Please address this issue.</p>	<p>The results of wildlife exposure modeling in the Revised SLERA indicated negligible potential for adverse effects to semi-aquatic wildlife potentially foraging within the Salem Canal. Except for chromium, low molecular weight (LMW) PAHs, and high molecular weight (HMW) PAHs, estimated daily doses (EDDs) based on maximum canal-wide exposure point concentrations of modeled constituents did not exceed Low TRVs (TRV_{Low}) derived from NOAEL-based endpoints for growth and reproduction. Refined EDDs for chromium, LMW PAHs, and HMW PAHs based on upper confidence limit of mean (UCL_{mean}) exposure point concentrations did not exceed NOAEL-based TRV_{Low} values. Given that none of the refined EDDs exceeded TRV_{Low}, the derivation of High TRVs (TRV_{High}) did not influence the overall risk characterization for semi-aquatic wildlife in the Revised SLERA. Based on the conservative exposure assumptions used in the modeling approach (e.g., 100 percent area use in areas of poor to marginal habitat quality), these results indicate that adverse effects to semi-aquatic wildlife due to exposure to COPECs in sediments are not likely.</p> <p>Further review of the TRVs used in the Revised SLERA indicate that some TRV_{High} values were based on LOAEL endpoints for growth and reproduction endpoints. Therefore, Appendix D of the Revised SLERA, specifically Table D4, will be updated to clarify the basis for TRV_{Low} and TRV_{High} for each individual COPEC included in wildlife exposure modeling. In some instances, TRVs were based on two-tiers of NOAEL-based TRVs (e.g., mammalian exposure to PAHs). However, TRVs for many metals were based on geometric mean NOAELs and geometric mean LOAELs for growth and reproduction endpoints from the Eco-SSL compilations (EPA, 2005). TRVs for pesticides and some semi-volatile organic compounds were also based on NOAEL- and LOAEL-based values compiled in Sample et al. (1996). As stated above, the TRV_{High} values did not influence the risk characterization given that most screening-level and all refined exposure estimates were below TRV_{Low} values. However, the basis for each TRV used in the modeling will be clarified in the Revised SLERA.</p> <p>In addition, the draft NJDEP policy update regarding the selection of TRVs that is proposed for the EE Technical Guidance will be reviewed. However, changes to the Revised SLERA based on this guidance will not be incorporated until the policy is finalized in next revision of the EE Technical Guidance.</p>
3	<p>7.2.3 Frequency of Detection: The SLERA states that "COPECs with detection frequencies of less than 5 percent were not evaluated further ." The magnitude of the exceedance and distribution of detections must also be taken into account prior to eliminating a COPEC from consideration at a site, consistent with Section 5.5 Ecological Evaluation Report of NJDEP 2015. Please address this issue.</p>	<p>The magnitude of exceedance and distribution of detections of COPECs eliminated based on low detection frequencies (less than 5 percent of samples) were limited and did not materially affect the overall risk characterization and conclusions presented in the Revised SLERA. As indicated in the response to EPA Comment #5, only five organic constituents were excluded as COPECs in bulk sediment or pore water based on low detection frequencies during COPEC refinement: 2-chlorophenol, bis(2-ethylhexyl)phthalate, o-toluidine, phenol, and carbazole. Of these COPECs, maximum detected concentrations of bis(2-ethylhexyl)phthalate, o-toluidine, and phenol in sediment resulted in hazard quotients (HQs) of 1.9 to 2.4. Maximum bis(2-ethylhexyl)phthalate concentrations in pore water resulted in HQs of 11.3 and 12.5 for the 0-0.5-ft and 0.5-0.75-ft intervals, respectively. In these pore water exposure intervals, bis(2-ethylhexyl)phthalate was detected in 1 of 38 samples (2.6 percent). The magnitude and distribution of detections of these COPECs will be discussed in the Revised SLERA and it will be stated that the exclusion of these COPECs does not materially affect overall risk characterization or conclusions.</p>

Responses to EPA/NJDEP Comments on the Revised Salem Canal Screening-Level Ecological Risk Assessment (11/24/17)
Chemours Chambers Works, Route 130
Deepwater, Salem County, New Jersey
NJDEP SRP PI# 008221
EPA I.D. Number: NJD 002385730

	EPA/NJDEP Comment	Chemours Response
4	<p>7.2.4 Comparison to Background Threshold Values: The SLERA states that "maximum and refined exposure point concentrations (EPCs) were compared to background threshold values (BTVs) to evaluate site data in the context of regional conditions." When comparing site data to background data, like statistics must be compared (i.e., maximum to maximum, average to average, etc.). Please address this issue.</p>	<p>Comparisons of maximum concentrations to background threshold values (BTVs) will be retained in the Revised SLERA; however, comparisons between refined EPCs based on UCLmean concentrations will be removed. The BTV is intended to represent the upper bound of background concentrations in a reference dataset. Comparisons of site and background data are typically conducted as 1) point-by-point comparisons of site data to the BTV and 2) background-site population comparisons (EPA, 2006). Comparison of the maximum site concentration to the BTV is essentially a point-by-point comparison. If the maximum site concentration is less than the BTV, then all remaining site points would also be less than the BTV. Consistent with the NJDEP comment, the Revised SLERA will be updated to remove comparisons of BTVs to refined EPCs based on UCLmean concentrations because these values are a conservative estimate of the center of the site data population. Instead of comparisons between BTVs and refined EPCs, the frequency of site samples exceeding a given BTV will be identified.</p>
5	<p>8.2.2 Refined Risk Characterization and SMDP - Scientific Management Decision Point: The SLERA states that "there is no need for remediation based on ecological risk".</p> <p>However, isolated hot spots do exist and should be evaluated in accordance with Section 6.4.4 Hot Spots of NJDEP 2015. Please address this issue.</p>	<p>The results of the Canal-Wide Investigation identified a limited number of stations located adjacent to outfalls within Reach 2 and the Tidal Reach with elevated concentrations of select metals and PAHs relative to ESVs or BTVs. Further characterization sampling will be proposed to define the extent of elevated concentrations in these localized areas. Following the additional characterization sampling, further risk evaluation will be conducted to assess the potential impacts of these localized areas on the assessment endpoints identified for the Canal-Wide Area in the Revised SLERA. Data from the additional characterization sampling will also be used to evaluate these localized areas as potential hot spots in accordance with Section 6.4.4 of the EE Technical Guidance.</p>
6	<p>Figures 17 and 22: These figures indicate elevated levels of mercury (3.36 mg/kg and 1.86 mg/kg) adjacent to Outfall Q.</p> <p>In accordance with Section 6.0 Technical Guidance for Preparing Ecological Risk Assessments of NJDEP 2015, "treatment and removal should be considered for sites where ecological risk is determined to be negligible if persistent, biomagnifying, toxic [contaminants] are present." Please address this issue.</p>	<p>Please see the response to NJDEP Technical Coordinator Comment #5. Further characterization sampling will be proposed to define the extent of elevated concentrations in these localized areas. Following the additional characterization sampling, further risk evaluation will be conducted to assess the potential impacts of these localized areas on the assessment endpoints identified for the Canal-Wide Area in the Revised SLERA.</p> <p>However, it should be noted that mercury EDDs calculated in the Revised SLERA based on the canal-wide maximum EPC within the biologically active zone (0-0.5-ft) did not exceed TRV_{Low} values for avian or mammalian receptors based on NOAEL-based endpoints for growth and reproduction.</p>
7	<p>Figures 18 and 23: These figures indicate elevated levels of mercury (2.41 mg/kg and 2.92 mg/kg adjacent to Outfall M; 1.45 mg/kg adjacent to Outfall H; 2.44 mg/kg adjacent to Outfall F; 1.77 mg/kg adjacent to Outfall E; and 1.83 mg/kg and 5 mg/kg adjacent to Outfall D) as well as PAHs (9.78 mg/kg and 11.295 mg/kg adjacent to Outfall M).</p> <p>In accordance with Section 6.0 Technical Guidance for Preparing Ecological Risk Assessments of NJDEP 2015, "treatment and removal should be considered for sites where ecological risk is determined to be negligible if persistent, biomagnifying, toxic [contaminants] are present." Please address this issue.</p>	<p>Please see the response to NJDEP Technical Coordinator Comment #5. Further characterization sampling will be proposed to define the extent of elevated concentrations in these localized areas. Following the additional characterization sampling, further risk evaluation will be conducted to assess the potential impacts of these localized areas on the assessment endpoints identified for the Canal-Wide Area in the Revised SLERA.</p> <p>However, as stated in the response above, mercury EDDs calculated in the Revised SLERA based on the canal-wide maximum EPC within the biologically active zone (0-0.5-ft) did not exceed TRV_{Low} values for avian or mammalian receptors based on NOAEL-based endpoints for growth and reproduction. EDDs for HMW and LWM PAHs calculated based on refined EPCs were below TRV_{Low} values.</p>

EPA I.D. Number: NJD 002385730

	EPA/NJDEP Comment	Chemours Response
8	<p>Figures 19 and 24: These figures indicate elevated levels of metals (1,210 mg/kg lead and 45.8 mg/kg arsenic adjacent to Outfall 013) as well as PAHs (22.907 mg/kg and 13.792 mg/kg adjacent to Outfall 011).</p> <p>In accordance with Section 6.0 Technical Guidance for Preparing Ecological Risk Assessments of NJDEP 2015, "treatment and removal should be considered for sites where ecological risk is determined to be negligible if persistent, biomagnifying, toxic [contaminants] are present." Please address this issue.</p>	<p>Please see the response to NJDEP Technical Coordinator Comment #5. Further characterization sampling will be proposed to define the extent of elevated concentrations in these localized areas. Following the additional characterization sampling, further risk evaluation will be conducted to assess the potential impacts of these localized areas on the assessment endpoints identified for the Canal-Wide Area in the Revised SLERA.</p> <p>However, it is important to note that EDDs calculated for lead and arsenic in the Revised SLERA based on the canal-wide maximum EPC concentrations within the biologically active zone (0-0.5-ft) did not exceed TRV_{Low} values for avian or mammalian receptors based on NOAEL-based endpoints for growth and reproduction. EDDs for HMW and LWM PAHs calculated based on refined EPCs were below TRV_{Low} values.</p>
9	<p>Toxicity Reference Values: As stated in 5.2.2 Wildlife Ingestion Pathway Evaluation, above, the SLERA uses a "Low TRV" and a "High TRV;" however, instead of using a NOAEL and LOAEL for the "Low TRV" and "High TRV," the SLERA uses two different NOAELs. Consistent with Section 6.1.3.3 Toxicity Reference Values, the HQ range should be bounded by a NOAEL and a LOAEL. NJDEP has a draft TRV Policy which will be incorporated into the next revision of NJDEP 2015. A portion of that policy is attached. Please address this issue.</p>	<p>Please refer to the response to NJDEP Technical Coordinator Comment #2.</p>
10	<p>Table D1: The home range for the Great Blue Heron is listed as 7-8 km (15,000-20,000 ha). Whereas this is correct, it is the foraging distance from the colony and the size of the Feeding Territory is 0.6 (fall) to 8.4 (winter) ha. When calculating an area use factor (AUF), the feeding territory should be used instead of the home range (foraging distance from colony) since the Great Blue Heron may travel a greater distance to a food source, but feed in a smaller area, once at a suitable feeding area. Given that an AUF of 1 was used in this document, it does not impact the calculations, but should be used if an AUF is considered in the future. Please address this issue.</p>	<p>Comment noted. The screening-level and refined wildlife exposure models presented in the Revised SLERA assumed 100 percent area use by representative receptors (i.e., AUF of 1.0) and the results indicated negligible potential for adverse effects to semi-aquatic wildlife. If further refinement of wildlife exposure models is warranted for great blue heron or other receptors with foraging ranges greater than the study area of the Salem Canal, foraging distance will be considered in the estimation of the AUF.</p>
11	<p>Whereas some of the NJDEP TRVs are higher than the Chambers Works TRVs, many are lower, sometimes by an order of magnitude. The choice of TRVs has a large impact on the risk calculation. Risk should be recalculated based on appropriate NOAELs and LOAELs in accordance with the NJDEP draft policy. Please address this issue.</p>	<p>Please refer to the response to NJDEP Technical Coordinator Comment #2.</p> <p>The draft NJDEP policy update regarding the selection of TRVs that is proposed for the EE Technical Guidance will be reviewed. However, changes to the Revised SLERA based on this guidance will not be incorporated until the policy is finalized in next revision of the EE Technical Guidance.</p>

	EPA/NJDEP Comment	Chemours Response
12	<p>Appendix E - Sediment Quality Benchmark (SQB) Documentation:</p> <p>2.0 Derivation of Sediment Quality Benchmarks: Thirteen of the twenty-seven COPECs listed as being derived for the SLERA have NJDEP ecological screening criteria (ESC). Whereas an RP may propose alternate ESC, justification must be provided for the alternate ESC. Chambers Works should provide justification for using each of the alternate ESC. Please address this issue.</p> <p>Table E1: Two of the six COPECs listed as being derived for the SLERA have NJDEP ESC. Whereas an RP may propose alternate ESC, justification must be provided for the alternate ESC. Chambers Works should provide justification for using each of the alternate ESC. Please address this issue.</p>	<p>When available, NJDEP ESCs were used in the screening-level exposure evaluation as a conservative estimate of potential risk. As specified in the Refined Exposure Evaluation (see Section 7.2) and documented in Appendix E of the Revised SLERA, alternate criteria that are protective of chronic exposure were derived to further focus the COPEC list and more accurately characterize potential risk. Alternate criteria derived in Appendix E incorporated predictive approaches, such as equilibrium partitioning (EqP) models, consistent with NJDEP EE Technical Guidance Section 6.2.2.3, to provide a more accurate measure of the bioavailability (toxicity) than simply screening bulk sediment data against screening values (NJDEP, 2015). The rationale for this approach was presented generally in Section 1.0 of Appendix E and the technical basis for the derivation of alternate criteria was presented in Section 2.0 of Appendix E. Further clarification is requested from NJDEP regarding the additional rationale and justification required in addition to the documentation provided in Appendix E for the use of these alternate criteria in the Refined Exposure Evaluation.</p>
DEP Ecological Risk Assessor Comments		
	<p>This reviewer has no comments to add to the Technical Coordinator's comments above.</p> <p>However, the following comments from review of the February 2017 Salem Canal Investigation Report are worth reiterating as they support the Department's disagreement with Chemours Revised SLERA conclusions that "no further ecological investigation or monitoring of the Canal-Wide Area is warranted and that future monitoring of the "potential for the degradation of seep-related constituents over time" within the Former Seep Area (as presented in the AECOM and EHS Support, 2017 Salem Canal Investigation Summary Report and the URS 2015 MNR Framework) is all that is required in the Former Seep Area. Please address this issue and the supporting issues listed below.</p>	<p>As indicated in the response to the NJDEP Technical Coordinator Comment #5, further characterization sampling will be proposed to define the extent of elevated concentrations in localized areas of elevated concentrations identified near outfall stations. Following the additional characterization sampling, further risk evaluation will be conducted to assess the potential impacts of these localized areas on the assessment endpoints identified for the Canal-Wide Area in the Revised SLERA.</p> <p>Further discussion of NJDEP issues raised from the review of the February 2017 Salem Canal Investigation Summary Report is provided below. Responses to specific comments on the 2017 Salem Canal Investigation Summary Report were provided to EPA and NJDEP on December 7, 2017.</p>
1	<p>Sediment sample SC-236-OutT2 (0.5-1.0), collected in the Tidal Reach, contains 118 ppm total PCBs. This high level appears to be a site-related constituent and needs to be delineated and addressed.</p>	<p>The total PCB concentration in sample SC-236-OutT2 (0.5-1.0) from the Tidal Reach was correctly posted as 118 µg/kg in the Revised SLERA. As noted in the response to comments on the 2017 Salem Canal Investigation Summary Report, a conversion error in the development of Figure 25 in the 2017 Salem Canal Investigation Summary Report resulted in an erroneous posting of 118,000 µg/kg.</p>

Responses to EPA/NJDEP Comments on the Revised Salem Canal Screening-Level Ecological Risk Assessment (11/24/17)

Deepwater, Salem County, New Jersey
NJDEP SRP PI# 008221
EPA I.D. Number: NJD 002385730

EPA/NJDEP Comment	Chemours Response
<p>2 Reach 2 sediment sample SC-1890utF9 (1.0'-2.5') contains the highest concentration of PFAs detected in the Salem Canal. The levels are much higher than those detected in the Reference Area of the canal and appear to be site-related. No sediment benchmark was provided; however, the extent of elevated levels of PFAs in canal sediments remains undelineated. This issue should not be bifurcated from the SLERA.</p>	<p>Please refer to the response to EPA General Comment #3 regarding the reporting of PFAS data collected in sediment and surface water samples in the Salem Canal.</p>
<p>3 If monitoring of the former Seep Area is the future course of action, it is recommended that bulk sediment monitoring sampling events be conducted more frequently than every 4 years as previously proposed by Chemours.</p>	<p>As proposed in the March 10, 2015 response to comments on the <i>Revised Bulk Sediment Sampling and Analysis Plan</i>, the frequency of bulk sediment monitoring was revisited following the analysis of data presented in the 2017 Salem Canal Investigation Summary Report and Revised SLERA. Based on this evaluation, a 4-year sampling frequency was recommended for bulk sediment monitoring.</p> <p>Key considerations in evaluating the sampling frequency included estimated recovery timeframes, particularly biodegradation and sedimentation rates, and the frequency of previous monitoring events. The 4-year period between post-SPB monitoring events (i.e., 2011, 2015, and 2019) was recommended to allow for a consistent time period between sampling events and to enable sufficient time to measure the potential attenuation of seep-related constituents resulting from biodegradation and physical isolation processes (i.e., sedimentation and burial of seep-related constituents below the BAZ). Maintaining a consistent time period between sampling would eliminate a potential confounding variable in interpreting changes between sampling events. Further, linear accumulation rates (LARs) of 1.1 cm/year (0.43 in/year) to 1.6 cm/year (0.62 in/year) for sediment calculated using radioisotope dating (see the 2017 Salem Canal Investigation Summary Report Appendix B Section 2.3.5) indicate that approximately 1.7 to 2.5 inches of sediment will accumulate over a 4-year period between sampling events. Based on an operational BAZ depth of 0-0.5-ft (0-6-in), the net accumulation of new sediment deposition between 2015 and 2019 would comprise the upper 28 – 40 percent of the operational BAZ. This time period is needed to provide sufficient time to monitor measurable changes in exposure within surficial sediments. In addition, annual sediment coring activities at 20 - 24 stations within the former seep area would result in frequent and unnecessary disturbance of surface and subsurface sediments. Therefore, it is recommended that the frequency of monitoring remain every four years as proposed in the 2017 Salem Canal Investigation Summary Report; the next bulk sediment monitoring event is proposed in 2019.</p>
<p>4 Levels of several inorganics detected in Tidal Reach and Reach 2 sediment samples exceed their Severe Effects Level Ecological Screening Criteria (ESLs) and background UTLs (i.e., chromium, copper, lead, and mercury). These elevated levels need to be addressed.</p>	<p>As indicated in the response to NJDEP Technical Coordinator Comment #5, the results of the Canal-Wide Investigation identified a limited number of stations located adjacent to outfalls within Reach 2 and the Tidal Reach with elevated concentrations of select metals and PAHs relative to ESVs or BTVs. Further characterization sampling will be proposed to define the extent of elevated concentrations in these localized areas. Following the additional characterization sampling, further risk evaluation will be conducted to assess the potential impacts of these localized areas on the assessment endpoints identified for the Canal-Wide Area in the Revised SLERA.</p>

EPA/NJDEP Comment	Chemours Response
<p>5 Sediment and surface water quality and associated ecological exposure in the Tidal Reach are influenced by both the Salem Canal and the Delaware River. Ecological data from the Tidal Reach are just as appropriately evaluated with data from the Salem Canal as they are with data from the Delaware River (Pertains to comments #1 and #4 above). Sediment or surface water impacts from historic or active outfalls should not be casually attributed to contaminant tidal influx from the Delaware River. In fact, the opposite cannot be ruled out.</p>	<p>As indicated in the response to comments on the 2017 Salem Canal Investigation Summary Report, it is understood that surface water and sediment data within the Tidal Reach of Salem Canal may be influenced by the non-tidal portion of Salem Canal, as well as by the Delaware River. Sediment and surface water data collected within the Tidal Reach of Salem Canal will be incorporated in future ecological exposure evaluations for the Delaware River upon completion of the perimeter sheet pile barrier intended to isolate groundwater migration from the site to the Delaware River.</p>

**Response to EPA Comment Letter dated December 7, 2015 (in error) Regarding the
Ecological Risk Assessment for the Salem Canal
DuPont Chambers Works
Deepwater, New Jersey**

Dear Mr. Tjho:

This letter provides responses to comments received from the United States Environmental Protection Agency (EPA) on the ecological risk assessment being completed for the Salem Canal at the E.I. du Pont de Nemours and Company (DuPont) Chambers Work complex. In a November 18, 2014 letter (received by DuPont on December 2, 2014), EPA requested that DuPont conduct a screening-level ecological risk assessment (SLERA) for sediment in the Salem Canal in accordance with EPA *Ecological Risk Assessment Guidance for Superfund* (ERAGs).

The November 18, 2014 EPA letter also requested that DuPont submit a technical memorandum prior to submitting the SLERA that provided a listing of constituents of concern (COCs), media of concern, exposure pathways and receptors, and a description of ecotoxicity screening values. DuPont responded to EPA comments and submitted the 2007 *Dyes Area and White Products Area Baseline Ecological Evaluation* (BEE) to EPA in lieu of the technical memorandum on December 15, 2014. As explained in greater detail below, the BEE contained the information that EPA requested to be provided within the technical memorandum. Following the transmittal of the 2007 BEE and the DuPont response to comments, EPA provided a letter with additional comments for the pending SLERA (letter dated December 7, 2015; in error) received via e-mail on January 13, 2015.

This letter provides responses to the comments contained in the EPA letter received on January 13, 2015. The text of the comments provided in the EPA letter is provided below in italics followed by the DuPont response.

EPA Comments Letter, received January 13, 2015

- In EPA's November 18 letter to you, the Agency requested, prior to completing the requested Screening Level Ecological Risk Assessment (SLERA), that DuPont submit a technical memorandum including: a list of contaminants of concern (COCs) proposed for inclusion in the SLERA; a list of media of concern; a list of exposure pathways and receptors to be included in the SLERA; and a description of ecotoxicity screening values and the sources of those values proposed for use in the SLERA. Instead of providing the*

requested information, DuPont responded to this request by providing a 2005 Report called Baseline Ecological Evaluation for Dyes and White Products. This was not responsive in any way to EPA's request and does not include any of the specifically requested information. It is unclear why DuPont provided this report. The report does not contain any information about the Salem Canal, which was the subject of EPA's request. COCs requested for Canal media (surface water and sediment). The most recent data collected in the Canal should be used (2008 and 2011), migration and exposure pathways should be determined for the canal media and the SLERA needs to use the most current NJDEP ecological guidance documents, ecotoxicity screening values, sediment and surface and groundwater sampling data. None of this is included in the report you submitted.

DuPont Response: The technical memorandum requested in the November 18, 2014 letter from EPA is attached to this letter. However, it is important to clarify that the report provided by DuPont [2007 Dyes Area and White Products Area Baseline Ecological Evaluation (BEE)] on December 15, 2014 was responsive and did contain the requested data and information on the Salem Canal. While the most recent surface water and sediment data were not contained in this report, the conceptual site model, which includes sources, constituents of concern, migration pathways, and receptors presented in the BEE, still remain relevant to the SLERA. Specific clarification for sending the BEE instead of a separate technical memorandum and where the requested information is located within the BEE is provided below:

- ❑ The Dyes Area and White Products Area BEE was required and was conducted in accordance with New Jersey Department of Environmental Protection (NJDEP) Technical Requirements for Site Remediation (Tech Regs) to evaluate whether there was a potential for Salem Canal to be impacted by groundwater from these former manufacturing areas. Hence, the title reflects the source area for the contamination. However, a cursory review of the document (specifically Figures B-3 and B-4) clearly indicates that the Salem Canal was evaluated.
- ❑ The BEE is a screening-level ecological evaluation that has similar objectives to the ERAGs SLERA requested by EPA. Because both documents have similar objectives, the BEE contained the information EPA requested for the Salem Canal regarding:
 - Contaminants of concern (COCs): See Section 2.0 (Data Evaluation) and Section 2.3 [Identification of COPECs, specifically section 2.3.1 (Sediment) and 2.3.2 (Surface Water) and associated tables].
 - Media of concern: See Section 2.0 (Data Evaluation) and Section 2.3 (Identification of COPECs, specifically Section 2.3.1 (Sediment) and Section 2.3.2 (Surface Water)].
 - Exposure pathways and receptors: See Section 3.0 [Environmental Sensitive Areas, specifically Section 3.1 (Salem Canal)] and Section 4.0 (Contaminant Migration Pathways).
 - Ecotoxicity screening values with associated sources: See Section 2.2 (Ecological Benchmarks).
- ❑ As noted in our submittal letter, EPA requested the Technical Memorandum by December 15, 2014; however despite the date on the request, the letter was not received by DuPont until December 2, 2014. With the ongoing efforts to meet other report

deadlines to EPA and in consideration that this BEE (previously submitted and approved by EPA and NJDEP) did provide the requested information, the submittal was therefore considered to be adequate to meet the intent of the EPA request in the November 18, 2014 letter.

Responses to specific comments in the above comment regarding the completion of the SLERA are provided below:

- ❑ As requested in the comment above, the most recent data for relevant exposure media will be evaluated in the SLERA to assess risk for identified migration and exposure pathways.
- ❑ Regarding relevant guidance documents, November 18, 2014 EPA specified ERAGs as the relevant guidance for conducting the SLERA. While relevant portions of NJDEP ecological guidance documents will be incorporated into the SLERA as appropriate, the SLERA will be structured consistent with ERAGs; the SLERA will not be developed in accordance with the Ecological Evaluation process prescribed in the NJDEP Tech Regs (N.J.A.C. 7:26E-1-16).

2. *The requested SLERA is required to determine if remedial action is necessary for contaminated media in the Salem Canal. In item 4 of your December 15 letter, you indicate that typically, a SLERA is done before the remedial action and that in this case, EPA is requesting it follows [sic] the remedial action. That is not a correct assessment. The remedial action taken was the installation of a sheetpile barrier wall to prevent contaminated groundwater on the plant property to continue to act as a source of contamination to the Salem Canal. EPA is not asking you to perform a SLERA for the contaminated groundwater for which an action has already been taken. EPA is asking you to perform a SLERA to evaluate ecological risks posted by surface water and sediment within the contaminated Salem Canal, for which no remedial action has been taken to date.*

DuPont Response: The purpose of the SLERA is to conduct a conservative, screening-level ecological risk assessment of the Salem Canal to evaluate the need for a more thorough assessment within the ecological risk assessment process prescribed by ERAGs. The SLERA is not intended to determine if remedial action is necessary, as indicated by EPA in the above comment.

The SLERA for the Salem Canal was completed consistent with ERAGs. A screening-level problem formulation was conducted to identify potential exposure media, complete and relevant ecological exposure pathways, and receptors of ecological concern. Quantitative exposure estimates and risk characterizations were completed for each identified exposure pathway to evaluate the need for further risk assessment in subsequent steps of the ERAGs process. Consistent with ERAGs, this approach provides a holistic, screening-level assessment of potential ecological risk in the Salem Canal.

3. *In item 5 of DuPont's December 15 letter, DuPont does not agree with the Agency that the SLERA include a possible future land use scenario with no man-made controls on the Canal. Man-made impacts to the Salem Canal in the vicinity of contaminated sediments are significant and include the operation of a dam and the extraction of significant amounts of surface water on a regular basis from the Canal. These details must be presented in the SLERA for a complete understanding of the ecosystem being evaluated. In addition, a*

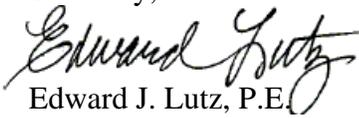

qualitative discussion of future land use scenario without man-made controls should be included. Further, consideration of the potential impacts of future climate changes on the Salem Canal, which could result in a higher frequency of storms and elevated water levels in the Delaware River should be discussed in the risk assessment.

DuPont Response: As stated in the December 15, 2014 response letter, DuPont does not foresee a future land use scenario with no-man made controls on the Salem Canal; current land use as an industrial facility is expected to remain in the future. Given that Munson Dam and the potable water intake are critical to the continued operation of Chambers Works and the freshwater supply to areas for miles upstream of the site, it is unlikely that any future scenario would include the removal of Munson Dam and the return of the Salem Canal to a brackish tidal channel with connectivity to the Delaware River. Such a change would not only impact the site, but the freshwater ecosystem of the Salem Canal for miles upstream of the site and potentially the Salem River.

Although DuPont believes that the uncertainty regarding impact of future land use scenarios on the seep area of the Salem Canal is low in the context of the widespread ecological changes that would occur due to the influence of brackish water, a qualitative discussion of future land use scenarios was included as part of the uncertainty analysis presented in the SLERA. The qualitative discussion includes general considerations regarding the removal of Munson Dam and the potential effects that climate change may have on the Salem Canal within the seep-area.

If you have any questions, please email me at Edward.J.Lutz@dupont.com or call me at 856-540-2077.

Sincerely,

Edward J. Lutz, P.E.

Memorandum

To	Sin-Kie Tjho, U.S. EPA Region 2	Page	1
CC	Edward Lutz, Project Director, DuPont Corporate Remediation Group Maryann Nicholson, DuPont Corporate Remediation Group		
Subject	Technical Support for the Salem Canal Screening-Level Ecological Risk Assessment (SLERA)		
		DuPont #:506020 AECOM: 18986658	
From	Gary Long		
Date	January 30, 2015		

AECOM prepared this technical memorandum on behalf of E.I. du Pont de Nemours and Company (DuPont) for the Salem Canal at the DuPont Chambers Works (the site) complex located in Deepwater, New Jersey. The memorandum was prepared in response to a request from the United States Environmental Protection Agency (EPA) in a letter dated November 18, 2014 (received by DuPont on December 2, 2014) to conduct a Screening Level Ecological Risk Assessment (SLERA) for sediment in the Salem Canal consistent with EPA *Ecological Risk Assessment Guidance for Superfund* (ERAGS; EPA, 1997). The overall objective of the SLERA is to evaluate potential risks to ecological receptors exposed to constituents of concern in environmental media within the Salem Canal that are associated with a former groundwater discharge from the site.

Prior to completing the SLERA, EPA requested the submittal of a technical memorandum that identifies constituents of concern (COCs), media of concern, exposure pathways and receptors, and a description of ecotoxicity screening values for the SLERA. On December 15, 2014, DuPont responded to EPA comments and submitted the 2007 *Dyes Area and White Products Area Baseline Ecological Evaluation* (BEE) to EPA in lieu of the technical memorandum. As explained in the response to comments letter that is attached to this memorandum, the BEE contained the information that EPA requested; however, EPA provided a letter (dated December 7, 2015; in error) indicating that the submittal of the 2007 BEE did not contain the requested information. This technical memorandum is being submitted to provide the requested information to support the SLERA and to address EPA concerns with the submittal of the 2007 BEE.

Purpose and Objectives

The purpose of this technical memorandum is to outline specific elements of the problem formulation and effects evaluation sections of the SLERA that were requested by EPA in the November 18, 2014 letter. Specific components of the SLERA requested by EPA include the following:

- Environmental Media of Concern
- Ecotoxicity Screening Values and their Sources

- Contaminants of Concern
- Exposure Pathways and Ecological Receptors

An ecological conceptual site model (ECSM) was developed as part of the problem formulation and effects evaluation in the SLERA to identify media of concern, ESVs, contaminants of concern and exposure pathways. The ECSM was developed from existing information about stressors, potential exposure, and predicted effects on an ecological entity (the assessment endpoint). As discussed in the BEE (DuPont CRG, 2007), prior to installation of a sheet pile barrier (SPB) to prevent the migration of impacted groundwater to the Salem Canal, groundwater discharge was the primary migration pathway to the canal sediment and surface water. The installation of the SPB effectively eliminated this migration pathway; however, constituents from the historical groundwater seep (seep-related constituents) remain in some environmental media within the canal. The following sections present the requested components of the problem formulation and effects evaluation portion of the SLERA.

Environmental Media of Concern

Consistent with exposure pathways identified in the ECSM, the presence of constituents of potential ecological concern (COPECs) in environmental media within the Salem Canal resulted from the historical discharge of impacted groundwater to surface water and sediment through the sidewall of the canal and upward through canal sediment. Based on these pathways, environmental media of concern evaluated in the SLERA included:

- Bulk sediment
- Sediment pore water
- Surface water

In accordance with the EPA letter received on January 13, 2015, the most recent analytical data for bulk sediment, sediment pore water, and surface water collected within the Salem Canal were used to evaluate ecological exposure in the SLERA. A summary of the number of environmental samples included the exposure evaluation is presented below; further information regarding sample locations and a summary of analytical data by medium is provided in the SLERA.

Descriptor	Bulk Sediment	Sediment Pore Water	Surface Water
Number of Sample Locations ^A	38	37	19
Years Evaluated	2009 and 2011	2009 and 2013	2009, 2011, and 2013

Notes:

A. Certain sample locations were sampled multiple times.

ESVs used to evaluate the direct contact exposure of benthic invertebrates and fish to seep-related constituents in sediment, pore water, and surface water are presented in the following section.

Ecotoxicity Screening Values

The screening-level effects evaluation established constituent exposure concentrations that represent thresholds for adverse effects. The following sections discuss the conservative screening criteria selected for the identification of COPECs and additional receptor-specific ecotoxicological data that may be used in exposure estimation and risk characterization. Benchmarks representing no observed effects concentrations (NOECs) were used preferentially. The following sections identify the hierarchy of ecological screening values (ESVs) that were used to evaluate organic COPECs from relevant exposure media including sediment, pore water, and surface water.

Sediment

The screening of seep-related constituents in sediment included a quantitative assessment of direct contact toxicity effects to benthic invertebrates consistent with the ECSM presented in the SLERA. ESVs used to evaluate concentrations of seep-related constituents in sediment are presented in Table 1; ESVs for sediment were obtained from the following hierarchy:

- NJDEP 2009: Freshwater Criteria Lowest Effects Levels (LELs)
- MacDonald et al. 2000: Consensus-based sediment quality guidelines for freshwater ecosystems
- EPA 2003b: Region 5 Ecological Screening Levels (Sediment)
- EPA 2006: EPA Region 3 Biological Technical Assistance Group (BTAG) Freshwater Benchmarks
- Washington State No Effect Level (NEL) Sediment Quality Standards
- Calculated ESVs based on an equilibrium partitioning (EqP) model (DuPont CRG, 1999).

Pore Water and Surface Water

ESVs used to evaluate seep-related constituents in aqueous exposure media, including pore water and surface water, are presented in Table 2. The following hierarchy of screening criteria/benchmarks was used to evaluate constituent concentrations in pore water and surface water:

- NJDEP 2009: Freshwater (FW2) Chronic Aquatic Criteria
- EPA 2009: National Recommended Water Quality Criteria (NRWQC)
- EPA 2003b: Region 5 Ecological Screening Levels (Water)
- EPA 2006: EPA Region 3 BTAG Freshwater Benchmarks
- EPA 1995: Region 4 Chronic Surface Water Screening Benchmarks
- EPA 2001: Region 6 Surface Water Screening Benchmark

- Suter, G.W., II, and C.L. Tsao. 1996: Tier II Secondary Chronic Values (SCVs)
- EPA 2011: Great Lakes Initiative Toxicity Data Clearinghouse aquatic life, chronic concentrations

Contaminants of Concern

Using the analytical data from relevant exposure media and the ESVs identified in the preceding section, COPECs were identified in the SLERA. COPECs identified in environmental media within the Salem Canal included volatile organic compounds (VOCs) and semi-volatile organic compounds (SVOCs), including polycyclic aromatic hydrocarbons (PAHs). Seep-related constituents evaluated for sediment and surface/pore water in the SLERA are presented in Tables 1 and 2, respectively.

Constituents were identified as COPECs based on the following criteria:

- Maximum exposure point concentration (EPC) exceeding an ecological screening value (ESV) and the laboratory method detection limit (MDL).
- No ESV was available.

No COPECs were identified in surface water samples collected in the Salem Canal since 2009. A summary of COPECs identified in the SLERA are presented below by exposure medium.

Constituent	Bulk Sediment	Pore Water
Volatile Organic Compounds		
Acetone	X	
Benzene	X	X
Chlorobenzene	X	X
Total xylenes	X	
1,1,2-trichlorotrifluoroethane	X	
Acetone	X

Constituent	Bulk Sediment	Pore Water
Semi-Volatile Organic Compounds (cont.)		
o-toluidine	X	X
Phenol	X	
Polycyclic Aromatic Hydrocarbons		
Naphthalene		X
Total PAHs	X	

Exposure Pathways and Ecological Receptors

The ECSM indicated that prior to installation of the SPB to prevent the migration of impacted groundwater to the Salem Canal, groundwater discharge was the primary migration pathway to the canal sediment and surface water. The installation of the SPB effectively eliminated this migration pathway; however, seep-related constituents remain in some environmental media within the canal.

Based on the evaluation of the chemical characteristics of seep-related constituents in the Salem Canal, direct contact exposures to bulk sediment, sediment pore water, and surface water are the primary routes of exposure to ecological receptors in the Salem Canal. As discussed in the SLERA, wildlife ingestion exposure pathways are not significant in the Salem Canal due to the limited potential for seep-related constituents to bioaccumulate from sediment or bioconcentrate from surface water into biological tissues. Given that direct contact exposure to COPECs is the predominant exposure pathway/route to ecological receptors in the Salem Canal, receptors of concern identified for evaluation in the SLERA include the following:

- Benthic invertebrates
- Fish

Exposure routes for benthic invertebrates include:

- Bulk sediment: direct contact/absorption within the biologically active zone (BAZ); direct/incidental ingestion
- Sediment pore water: direct contact/absorption within BAZ
- Surface water: direct contact/absorption

Benthic invertebrates are the most susceptible to the effects of seep-related constituents because of their sedentary nature and direct exposure to sediment and sediment pore water. As a result of this exposure, benthic invertebrates are sensitive to both acute and chronic changes in sediment quality. For benthic invertebrates, exposure occurs within the BAZ of sediment, which operationally extends from the sediment-surface water interface (SWI) to a depth of approximately 0.5 feet (6 inches) for freshwater sediment (EPA, 2001a). However, in environments similar to the Salem Canal with highly organic, fine-grained sediments and limited flow, the BAZ often does not extend as deep as 0.5 feet due to oxygen depletion in reducing sediment (EPA, 2001a). For the purposes of the conservative screening-level evaluation, the BAZ was considered to extend from 0 – 0.5 feet below the SWI.

Direct contact exposure to seep-related constituents in sediment pore water is a more relevant exposure route for benthic invertebrates when compared to bulk sediment exposure. Numerous studies indicate that sediment pore water concentrations are a better predictor of constituent bioavailability and toxicity to benthic invertebrate receptors when compared to bulk sediment concentrations (EPA, 2005; EPA, 2003a; NJDEP, 2012; Parkerton and Maruya, 2013). The bioavailability and toxicity of seep-related organic constituents in sediment are influenced by sediment physiochemical characteristics, including the quantity and type of organic carbon, which affects the partitioning of constituents between sediment and pore water. Site-specific measurements of freely dissolved concentrations in sediment pore water (C_{free}) are the most direct indicator of constituent bioavailability and partitioning when compared to other approaches to estimate C_{free} in pore water, including equilibrium partitioning (EqP) models from bulk sediment (DOD, 2009; Parkerton and Maruya, 2013).

Fish were selected as receptors of concern because of continuous direct contact with surface water. Exposure routes for fish include the following:

- Surface water: direct contact/absorption

Summary

The elements described in this technical memorandum were used in the problem formulation and effects evaluation sections of the SLERA conducted on the Salem Canal. As discussed in the SLERA, an ECSM was developed to identify relevant migration and exposure pathways from sources to environmental media and ecological receptors. Based on the ECSM presented in the SLERA, a conservative screening evaluation was conducted to assess the potential risk associated with exposure of benthic invertebrates and fish to COPECs identified in bulk sediment, sediment pore water, and/or surface water. Primary exposure pathways for benthic invertebrates include direct contact/absorption and the ingestion of sediment. Exposure pathways for fish include direct contact/absorption from surface water. COPECs identified in sediment and pore water within the Salem Canal included VOCs and SVOCs, including PAHs.

RE: Responses to April 9, 2015 and April 28, 2015 EPA and NJDEP Comment Letters on the January 2015 Salem Canal Screening-Level Ecological Risk Assessment DuPont Chambers Works Deepwater, New Jersey

Dear Mr. Tjho:

This letter provides responses to comments received from the United States Environmental Protection Agency (EPA) and New Jersey Department of Environmental Protection (NJDEP) on the Screening-Level Ecological Risk Assessment (SLERA) that was completed for the Salem Canal adjacent to the Chambers Work facility in Deepwater, New Jersey. The SLERA was submitted to EPA and NJDEP on January 30, 2015. Partial EPA comments were received on April 9, 2015 and additional EPA comments were received on April 28, 2015. A teleconference was convened between, EPA, NJDEP, and Chemours on June 23, 2015 to discuss the comments and proposed responses to select comments. This letter provides responses to the comments contained in both EPA letters and reflects agreements that were reached in discussions during the June 23, 2015 teleconference.

As agreed to during the June 23, 2015 teleconference, the SLERA will be revised based on the EPA comments presented in this response letter and additional analytical data that are scheduled to be collected in 2015. In addition to the SLERA, a Bulk Sediment Sampling and Analysis Plan (SAP) for the Salem Canal is currently under EPA and NJDEP review. A Peeper SAP is also currently in development to collect additional pore water data to support the SLERA and the Monitored Natural Recovery (MNR) Framework submitted on February 6, 2015. The incorporation of these additional bulk sediment and pore water data into the revised SLERA will enable a more comprehensive evaluation of current exposure conditions in the Salem Canal and will be useful in addressing some of the uncertainties identified in the January 2015 draft of the SLERA. Chemours recommended that the revised SLERA include these data to provide a more complete assessment of potential ecological risk to better inform the ecological risk assessment process for the Salem Canal; EPA and NJDEP concurred with this recommendation during the June 23, 2015 teleconference.

Responses to EPA comments contained in the letters received on April 9, 2015 and April 28, 2015 are presented below; the text of the comments provided in the EPA letters is presented in

italics followed by the DuPont response. In cases where the subject of successive comments was similar, a single response is provided for those comments.

EPA Comment Letter, received April 9, 2015

General Comments:

- 1. The 2007 Baseline Ecological Evaluation for Dyes and White Products Areas Report (Appendix B of the Salem Canal Interim Remedial Action Work Plan) indicates that several metals including antimony, arsenic, beryllium, cadmium, copper, lead, mercury, nickel, selenium, and zinc were found in shallow, mid-range, and deep soil samples as well as groundwater samples but sediment and surface water samples within the Salem Canal were not analyzed for these metals. If available, any metals data from surface water and/or sediment samples within Salem Canal should be presented in this SLERA report. If not available, an explanation as to why metals were excluded from analysis should be presented.*

DuPont Response: Sediment and surface water samples within the Salem Canal were not analyzed for metals because metals were not considered to be mobile in shallow groundwater entering the canal. As presented in the 2007 Baseline Ecological Evaluation for Dyes and White Products Areas Report [Appendix B of the Salem Canal Interim Remedial Action Work Plan; DuPont Corporate Remediation Group (CRG), 2007], an unfiltered sample from the groundwater seep was analyzed for metals in 2002. Only 4 of 13 metals (arsenic, copper, nickel, and silver) were detected in the seep sample; only silver was detected at a concentration that exceeding a surface water screening criterion (Tier II Secondary Chronic Value). Based on the limited detections and low concentrations of metals measured in the seep samples relative to surface water quality criteria, metals were not considered to be mobile in shallow groundwater at concentrations that would impact sediment or surface water quality. As a result, further investigations of sediment and surface water in the Salem Canal focused on potential impacts associated with volatile organic compounds (VOCs) and semi-volatile organic compounds (SVOCs) discharging to the canal via the groundwater seep. A brief discussion of the evaluation of metals in the seep sample will be added to the SLERA. In addition, the revised SLERA will evaluate analytical results for metals in shallow groundwater from B Aquifer that historically had the potential to discharge to the Salem Canal; these data will be summarized with the seep sample to assess the potential contribution of metals to sediments within the canal.

- 2. Section 4.3 contains information on Fate and Transport Characteristics based on DuPont's 2013 biodegradation research on Salem Canal groundwater and sediment. This information is too complex for a SLERA report and should be removed. It should be replaced with a more basic description of how COCs moved from soil to groundwater at the Dyes and White Products Area to Salem Canal sediment. The 2013 research information can be used to help determine if and what remedial action needs to be taken in the Salem Canal.*

DuPont Response: The discussion of site-specific biodegradation research is fundamental to the conceptual site model (CSM) for the Salem Canal because biodegradation is an important fate process for seep-related constituents. The SLERA included a summary-level review of the extensive research conducted to date to understand site-specific biodegradation processes

in Salem Canal media (Section 4.3) because of the importance of biodegradation in the fate of seep-related constituents. The SLERA refers the reader to the *Salem Canal Groundwater Remedial Action Progress and Sediment Investigation Status Report* (URS, 2013) for a more thorough discussion of the biodegradation research.

Given the importance of biodegradation processes in the CSM for the Salem Canal, it is appropriate to provide at least a summary-level review of the biodegradation research conducted to date. In addition to this summary level review of biodegradation, additional general discussion of seep-related constituent transport pathways from the Dyes and White Products Areas to Salem Canal sediment will be provided in the revised SLERA.

3. *If available, the results of any wildlife surveys at the Salem Canal, other areas of the facility, or the whole facility should be presented in this report. This would provide information as to what terrestrial, aquatic, and avian species are present or expected at the facility.*

DuPont Response: Focused wildlife surveys were conducted as part of the Ecological Investigation of the Manufacturing and Carneys Point Areas of Chambers Works (URS, 2009). However, these surveys were not focused on the areas surrounding the Salem Canal; these surveys were conducted in other areas of Chambers Works (e.g., Carneys Point) with cover types that are substantially different than cover types surrounding the canal.

As described in Section 3.1 of the SLERA and illustrated in the attached photographs, the segment of the Salem Canal within the Chambers Works property is a poor quality freshwater environment that has limited adjacent riparian/terrestrial habitat value for wildlife. There is no vegetated riparian zone associated with the northern shoreline of the canal, with facility roads, parking lots, or buildings extending to the top of the canal banks in most places. The 2009 Ecological Investigation did not identify ecological exposure areas in the Manufacturing Area adjacent to the north of the Salem Canal. The banks on the north side of the canal are steep and armored with concrete, asphalt, and aggregate rubble for shoreline protection. The banks on the south side of the canal have a limited riparian zone consisting of invasive herbaceous vegetation, including *Phragmites australis* (common reed). The adjacent terrestrial areas to the south of the Salem Canal are developed into parking lots with surrounding lawns that are mowed and maintained. There is little to no riparian cover to create a canopy to shade the canal or to provide cover for wildlife. These cover types surrounding the Salem Canal result in poor quality habitat with limited value for wildlife. Representatives of EPA and NJDEP are encouraged to visit Chambers Works to observe the ecological setting of the Salem Canal and its surroundings.

Specific Comments:

1. *p. 14, Section 4.5 and Figure 4-1 - Fish that consume benthic invertebrates, as well as aquatic birds and mammals, come into contact with bulk sediment and sediment pore water as a consequence of their feeding habits. Although the exposures to sediment and pore water may be short-term and minimal for these receptors, they should be included in this section as well as in Figure 4-1.*

DuPont Response: As discussed and agreed to during the June 23, 2015 teleconference, the ecological conceptual site model (ECSM) will be revised to include potentially complete

pathways for demersal fish that may contact bulk sediment and pore water as a consequence of their feeding habits. As indicated in the above comment, these exposures are likely short-term and minimal and may not be quantifiable in the SLERA due to limited toxicity data for these pathways. Therefore, the revised ECSM will distinguish between primary pathways that will be quantitatively evaluated in the SLERA and secondary pathways that may be complete, but are not quantitatively evaluated.

2. *p. 27, Section 7.1.5 – This section is described as presenting the “detailed results” for bulk sediment and pore water COPEC refinement; however information seems to be missing. Table 6.2 (bulk sediment 0-0.5 ft) shows 28 constituents with maximum concentrations greater than ESVs but Table 7.1 only shows 4 constituents. There is no information as to what happened to the other 24 constituents greater than ESVs.*

DuPont Response: The SLERA will be revised to more clearly present the progression from the preliminary exposure evaluation to the refined exposure evaluation for sediment. Table 6.2 presents a preliminary direct contact evaluation based on the most conservative exposure scenario, which compares a maximum concentration to a conservative ESV. As described in Section 7.1, Table 7.1 presents a refined direct contact evaluation based on comparisons of 95 percent upper confidence limit (UCL₉₅) exposure concentrations to refined ecological benchmarks. Table 7.1 will be modified to include each constituent from Table 6.2 with maximum concentrations exceeding ESVs to clarify the progression from the preliminary direct contact evaluation to the refined direct contact evaluation.

EPA Comment Letter, received April 28, 2015

1. *3.1 Habitat Description: The SLERA states that the canal is “approximately 7,000 feet long and 200 feet wide.” Scaling on GIS indicates that the canal is closer to 10,000 feet long. DuPont should confirm the canal’s length.*

DuPont Response: The SLERA will be revised to indicate that the total length of the Salem Canal is approximately 10,000 feet, as measured from Brown Dam on the Salem River to the Delaware River; the length of the Salem Canal from the entrance of Chambers Works (Canal Road and Route 130) to the Delaware River is approximately 5200 feet.

2. *4.1 Constituents of Potential Ecological Concern: In addition to total PAHs, individual PAH concentrations must be evaluated. The SLERA derived sediment quality benchmarks (SQB) for total PAHs using geometric means of recommended Threshold Effect Concentrations (TECs) and Probable Effect Concentrations (PECs) (Jones, Suter, and Hull, 1997); however, as noted on page 14 of the SLERA, “Based upon the additive toxicity of PAHs in pore water and the occurrence of PAHs as mixtures in the environment, EPA guidance recommends the evaluation of direct contact toxicity of PAH mixtures based on the sum of toxic units (TUs) for individual PAHs estimated in pore water using EqP (EPA, 2003a). DuPont is requested to detail how their approach addresses this recommendation.*

DuPont Response: The preliminary direct contact evaluation for PAHs in bulk sediment summarized in Table 6.2 of the SLERA included comparisons of maximum concentrations for individual PAH compounds to available ESVs for individual PAH compounds. The refined direct contact evaluation (Section 7.1) included a comparison of UCL₉₅

concentrations for total PAHs (tPAHs) to a refined ecological benchmark for tPAHs derived as the geometric means of recommended Threshold Effect Concentrations (TECs) and Probable Effect Concentrations (PECs) (Jones, Suter, and Hull, 1997). As previously stated above in the response to Comment #2 (page 4), Table 7.1 will be modified to clarify the progression from the preliminary direct contact evaluation to the refined direct contact evaluation.

As stated in the SLERA and the above comment, EPA recommends that exposure to PAH compounds be evaluated as a mixture due to the additive toxicity individual compounds and the occurrence of PAH mixtures in the environment (EPA, 2003). Therefore, the SLERA will be revised to include an evaluation of PAH mixtures in bulk sediment, consistent with guidance presented in EPA (2003). The evaluation of PAH mixtures will be included in the refined direct contact evaluation to augment the comparisons of UCL₉₅ tPAH concentrations to the refined ecological benchmark for tPAHs.

3. *4.4.2 Bioconcentration: The SLERA states that “a bioconcentration factor (BCF) is the unitless ratio of a constituent concentration in the tissue of an aquatic organism to the concentration in the ambient water.” The BCF may also be related to sediment and/or food. Therefore, this statement should be revised.*

The SLERA states that “PAHs and 1,2,4-TCB have log BCF values greater than 3; however, neither constituent has been detected in surface water within the Salem Canal.” These contaminants are present in sediment and potentially complete pathways via ingestion of macroinvertebrates and detritus, as well as incidental ingestion of sediment, exist. Therefore, these contaminants need to be assessed.

DuPont Response: Definitions of terms will be clarified in the revised SLERA.

Bioconcentration factor (BCF) is a general expression of the ratio of the contaminant concentration in tissue to the concentration in the surrounding exposure medium. BCF values for fish are commonly the ratio of tissue concentrations to water concentrations, as expressed in this section of the SLERA that addressed the accumulation of constituents in fish tissue from water. The SLERA discussed bioaccumulation (See Section 4.4.1) as the accumulation of constituents in tissues through ingestion pathways.

The SLERA indicated that bioaccumulation pathways were limited in the Salem Canal based on the characteristics of seep-related constituents of potential ecological concern (COPECs) and the relatively limited spatial area of potentially-impacted sediments. Based on the chemical characteristics published in the literature (e.g., $\log K_{ow} \leq 3.5$ and $\log \text{fish BCF} < 3$), the SLERA indicated that most seep-related COPECs were not likely to bioaccumulate or bioconcentrate in aquatic tissues. The importance of bioaccumulation pathways is further diminished by the limited spatial area of potential seep-impacted sediments relative to the typical foraging ranges of fish and wildlife resources that may use the Salem Canal. Collectively, these factors indicate limited potential exposure to seep-related COPECs via bioaccumulation pathways.

Although bioaccumulation pathways are limited for most seep-related COPECs, further evaluation of the potential bioaccumulation pathways for 1,2,4-TCB and PAHs will be

included in the revised SLERA. 1,2,4-TCB and PAHs were the only seep-related COPECs with $\log K_{ow} > 3.5$ and $\log \text{fish BCF} > 3$, indicating some potential for bioaccumulation or bioconcentration in tissue. As discussed and agreed to during the June 23, 2015 teleconference, bioaccumulation pathways for 1,2,4-TCB and PAHs will be evaluated in the revised SLERA using conservative literature-based biota-sediment accumulation factors (BSAFs), as available, and site-specific bulk sediment concentrations to estimate seep-related COPEC concentrations in tissue. The estimation of 1,2,4-TCB and PAH concentrations in benthic invertebrate and fish tissue will enable an evaluation of potential exposure to these receptor groups, as well as potential exposure to upper trophic consumers of benthic invertebrates and fish using dose rate modeling. The screening-level problem formulation (Section 4.0) of the SLERA will be revised to reflect the evaluation of bioaccumulation pathways for these constituents and the associated modifications to assessment and measurement endpoints.

4. *4.5 Exposure Routes and Receptors of Concern: The SLERA states that “limited potential for seep-related constituents to bioaccumulate from sediment or bioconcentrate from surface water into biological tissues” exists. The most accurate way to assess bioconcentration to biological tissue is to measure the concentration within the biological tissue. Therefore, DuPont should consider tissue sample collection and analysis.*

The SLERA states that “exposure routes for fish include ... surface water: direct contact/absorption.” Consumption of benthos and incidental ingestion of sediment is also an exposure route for fish and should be added.

5. *4.6 Assessment and Measurement Endpoints: The SLERA states that “comparison of COPEC concentrations in surface water to ecotoxicity benchmarks for fish” should be evaluated as measurement endpoints. Given that fish will also be exposed to COPECs via consumption of benthos and incidental ingestion of sediment, DuPont should add these measurement endpoints.*

DuPont Response to Comments 4 and 5: As stated in the previous response, 1,2,4-TCB and PAHs are the only seep-related COPECs with the potential bioaccumulate or bioconcentrate. As discussed and agreed to during the June 23, 2015 teleconference, further evaluation of bioaccumulation pathways for these COPECs will be conducted using conservative literature-based BSAFs. If the evaluation of tissue concentrations based on conservative BSAFs indicates limited potential for exposure via bioaccumulation pathways, the collection of biological tissues in the Salem Canal will not be warranted. If the collection and analysis of biological tissues is warranted based on the bioaccumulation evaluation, a biological field survey may necessary to determine if sufficient biomass exists for target organisms to conduct tissue analyses.

As previously stated (in response to comment #1 on page 3), the ECSM will be revised to include potentially complete pathways for demersal fish that may contact bulk sediment and pore water as a consequence of their feeding habits. However, the revised ECSM will distinguish between primary pathways that will be quantitatively evaluated in the SLERA and secondary pathways that may be complete but are not quantitatively evaluated. As previously stated, the screening-level problem formulation (Section 4.0) of the SLERA will be revised to

reflect the evaluation of bioaccumulation pathways for these constituents and the associated modifications to assessment and measurement endpoints.

6. *6.2.1 Bulk Sediment: The SLERA states “Maximum concentrations of most volatile COPECs were in samples collected in 2011 at stations SCD100 and SCD103, which were located adjacent to where the seep was observed.” This statement is a little misleading in that these samples were collected from mid-channel of the Salem Canal, not close to the sheet pile barrier or the immediate vicinity of the seep (see Figure 5-1 of the SLERA).*

DuPont Response: The SLERA will be revised to clarify the location of stations SCD100 and SCD103, which were located towards the middle of the channel adjacent to the location of the former seep.

7. *6.3 Preliminary Risk Characterization and SMDP: The SLERA indicates that bulk sediment and sediment pore water sampling should be conducted to address exposure to benthic invertebrates. DuPont should also consider toxicity testing to address benthic invertebrate exposure.*

Some species of fish feed on benthic organisms present in sediments. Sediment ingestion by fish needs to be evaluated. Additionally, exposure to piscivorous biota needs to be evaluated.

See comment in 4.6 Assessment and Measurement Endpoints, above.

8. *7.1 Refined Direct Contact Evaluation: The SLERA discusses refining the direct contact evaluation for benthic invertebrates. DuPont should also consider toxicity testing and bioaccumulation studies to address benthic invertebrate exposure.*

DuPont Response to Comments 7 and 8: Given the poor habitat quality in Salem Canal sediments, characterized by fine-grained sediments and relatively high total organic carbon (TOC) content (~3 percent), the results of a sediment toxicity testing program may be confounded by the introduction of potential non-COPEC-related stressors (e.g., ammonia, sulfide, grain size). These stressors may be introduced through the extraction and manipulation of sediment, resulting in ex situ exposure conditions in the laboratory that are not representative of in situ exposure conditions in Salem Canal. Potential effects on test endpoints that may be attributed to these stressors and not seep-related COPECs will likely make it problematic to develop a reliable dose-response relationship. Furthermore, the overall poor habitat quality in the Salem Canal in the absence of seep-related COPECs may limit the overall diversity and abundance of benthic invertebrates inhabiting the sediment. A benthic community limited by poor quality habitat similar to that observed in the Salem Canal may only support the most tolerant taxa, thereby making standard test organisms inappropriate and not representative of the native community. Given the potential costs and impacts to schedule associated with the implementation of a sediment toxicity testing program, the technical limitations and the potential for limited usability of data generated from a toxicity testing program in the Salem Canal must be considered.

Given the technical limitations of implementing an ex situ toxicity testing program in the Salem Canal, additional measurements of pore water are recommended to further evaluate benthic invertebrate exposure conditions prior to the consideration of toxicity testing. As

stated in the SLERA, site-specific measurements of seep-related constituents in pore water represent the most direct evaluation of constituent-specific bioavailability and potential toxicity to benthic invertebrate receptors in Salem Canal. Numerous studies indicate that pore water concentrations are a better predictor of constituent bioavailability and toxicity to benthic invertebrate receptors than bulk sediment concentrations (EPA, 2005; EPA, 2003; Parkerton and Maruya, 2013). Direct measurements of pore water enable an evaluation of the potential for seep-related COPECs to exert a toxic effect on benthic invertebrate receptors; therefore, these data may be used to separate the potential effects associated with seep-related COPECs from other undetermined stressors that may result in a toxic endpoint in a sediment toxicity test.

The SLERA and the Monitored Natural Recovery (MNR) Framework document (URS, 2015) indicated that available pore water data to evaluate exposure are limited. Therefore, more extensive pore water sampling will be proposed as part of a pore water SAP developed within the MNR Framework to provide additional data to directly evaluate potential benthic invertebrate exposure to seep-related COPECs. It is recommended that further evaluation of benthic invertebrate exposure based on these additional pore water data be completed prior to consideration of implementing a sediment toxicity testing program.

As stated in the response to Comments #4 and #5 on page 6, further evaluation of bioaccumulation pathways for these COPECs will be conducted using conservative literature-based BSAFs. It is recommended that these evaluations be conducted before considering bioaccumulation studies to evaluate potential effects to benthic invertebrates or other bioaccumulation pathways.

See the response to Comments #4 and #5 above regarding the evaluation of exposure to fish and piscivorous biota and associated modifications to the ECSM and problem formulation presented in the SLERA.

9. *7.1.1 Data Used in the Refinement: The SLERA utilized sediment and pore water data from the 0 to 0.5-foot interval only. Sediment and pore water data from the 0.5 to 1.0-foot interval must also be evaluated. Many COPEC concentrations are higher in the deeper interval than in the shallow interval and upward mobility of COPECs from the deeper interval is a concern to the Department.*

DuPont Response: Sediment and pore water data from the 0.5 to 1.0-foot interval were evaluated in the preliminary exposure evaluation presented in the SLERA. The preliminary evaluation presented the most conservative exposure scenario for sediment and pore water (maximum concentrations compared to conservative ESVs) for the 0 – 0.5' and 0.5 – 1.0' sediment intervals (see Tables 6-3 and 6-5, respectively).

The potential upward mobility of seep-related constituents from deeper sediments will be further evaluated as part of the data gap analysis presented in the MNR Framework document (URS, 2015). In the data gap analysis conducted on the post-sheet pile barrier CSM, the MNR Framework identified advection, dispersion, sorption, and decay processes within the underlying sediment (i.e., deeper sediment) and aquifer matrix as potential secondary sources of seep-related constituents to the biologically active zone (BAZ). Existing vertical pore

water concentration profiles generated from peeper sampling that indicate low concentrations of chlorobenzene in the BAZ relative to deeper intervals, indicating that any potential upward mobility of chlorobenzene is not impacting the BAZ. In addition to these existing data, the MNR Framework indicated that further evaluation of potential secondary sources to the BAZ is warranted and stated that a data quality objectives (DQO) process would be initiated to determine the additional data necessary to evaluate potential secondary sources. The approach for collecting these additional data will be presented in a subsequent sampling and analysis plan developed within the MNR Framework (URS, 2015).

10. 7.1.5 Pore Water: *The temporal comparison of paired 2009 and 2013 pore water data from 2 locations and subsequent general claim that an overall reduction in chlorobenzene exposure concentrations is occurring is not well supported. This information has been carried forward in the SLERA and interpreted to say that "...findings indicate limited potential for adverse effects to the survival, reproduction, and growth of benthic invertebrates within the BAZ" (see page 31, Section 7.3, Refined Risk Characterization and SMDP). A long-term, decreasing concentration trend needs to be demonstrated through annual sampling.*

The statement that the BAZ in the Salem Canal may not extend as deep as 6-inches (15cm) due to the highly organic, fine-grained sediments and limited flow has not been proven. Aquatic worms, in particular, may utilize this zone.

DuPont Response: The statement regarding the reduction in chlorobenzene exposure concentrations referenced in the above comment indicated that there was an overall reduction in chlorobenzene exposure concentrations at two paired sampling stations between 2009 and 2013. While this finding is specific to the temporal comparisons of chlorobenzene concentrations in these two paired stations, it is consistent with the CSM regarding the fate of chlorobenzene in sediments, particularly within the BAZ. It is also important to note that these paired stations were biased to the area of greatest chlorobenzene concentrations in 2011 sediment samples.

While the findings of this paired comparison are consistent with the CSM, it is acknowledged that the collection of additional pore water data is warranted. The SLERA and MNR Framework document identified the need for additional pore water data to address spatial and temporal uncertainties associated with post-SPB pore water datasets (URS, 2015). Based on this data gap analysis, a pore water SAP is being developed to support exposure evaluations presented in the SLERA, as well as the evaluation of natural recovery processes outlined in the MNR Framework.

The refined evaluation (Section 7.1) focused on ecological exposure in the 0 – 0.5 foot sampling interval because this is the interval where the greatest biological activity occurs and represents exposure that may result in population and/or community-level impacts. A review of bioturbation layer thickness in freshwater sediments indicates that nearly all direct contact exposure to benthic invertebrate receptors occurs within the top six inches of sediment. Based on work by Thoms et al. (1995), Reible (2008) estimated that the median bioturbation depth in freshwater environments was 4.8 cm (0.15 feet) and the 90th percentile bioturbation depth was 10 cm (0.33 feet). Although a site-specific evaluation of the BAZ in the Salem Canal has not been conducted, it is likely that the BAZ may not extend as deep as 0.5-feet due to the

highly organic, fine-grained sediments due to oxygen depletion in reducing sediment (EPA, 2001). However, for the purposes of a conservative screening-level evaluation, the 0 – 0.5 foot sampling interval was assumed to be representative of the greatest biological activity and exposure that may result in population and/or community-level impacts.

Monitoring frequency to support the demonstration of natural recovery of sediments in the Salem Canal will be addressed within the conceptual approach presented in the MNR Framework document (URS, 2015).

11. *7.3 Refined Risk Characterization and SMDP: The SLERA states that “pore water data are more reliable in predicting the bioavailability and toxicity of seep-related constituents.” Tissue sampling, toxicity testing and bioaccumulation studies are the most accurate and reliable methods. Therefore, DuPont should consider tissue sampling, toxicity testing and bioaccumulation studies to address benthic invertebrate exposure.*

DuPont Response: The statement cited in the above comment was in reference to the reliability of pore water in predicting the bioavailability and toxicity of seep-related constituents relative to bulk sediment.

While toxicity testing, tissue sampling, and bioaccumulation studies are potential methods to evaluate benthic invertebrate exposure, it is recommended that additional pore water sampling with peepers be conducted to evaluate constituent-specific exposure prior to consideration of these additional methods. Please refer to the responses to Comments #4 and #5 (page 6) regarding the consideration of tissue sampling/bioaccumulation testing and the responses to Comments #6 and #7 regarding the consideration of toxicity testing.

12. *8.1.2 Constituent Bioavailability: The SLERA states that “if the absorption of the chemical at the site is lower than observed in the laboratory study, exposure will be overestimated.” Likewise, if the absorption of the chemical at the site is greater than observed in the laboratory study, exposure will be underestimated. Therefore, DuPont should state this as well.*

DuPont Response: The possibility of greater chemical absorption at the site will be included in the uncertainty discussion in the revised SLERA; however, because the SLERA assumed 100 percent bioavailability relative to test compounds in laboratory toxicity studies it is more likely that absorption of the chemical at the site is lower than absorption in the laboratory study.

13. *Figure 4-1 Ecological Conceptual Site Model: The figure does not include incidental ingestion of bulk sediment as a potential exposure pathway for fish. DuPont should add this potential exposure pathway to the figure.*

DuPont Response: Please see the response to Comment #1 on page 3. The ECSM will be revised to include potentially complete pathways for demersal fish that may contact bulk sediment and pore water as a consequence of their feeding habits. However, the revised ECSM will distinguish between primary pathways that will be quantitatively evaluated in the SLERA and secondary pathways that may be complete but are not quantitatively evaluated.

14. *Sample Locations: A figure similar to figure 5-1, showing concentration isobars, would help visualize COPEC impacts and should be included in this SLERA.*

DuPont Response: The revised SLERA will present a figure illustrating the sediment data to help visualize the spatial distribution of seep-related COPEC concentrations. Potential options for visualizing the data will be evaluated based on the existing data at the time the SLERA is revised.

15. *Table 7-1: Refined Direct Contact Evaluation of Sediment (0-0.5 feet) Based on UCL95 Exposure Point Concentrations – Despite the level of data manipulation employed in the SLERA, the omission of aniline from the list of constituents is puzzling given it has an Ecological Screening Benchmark of 1 ppb (DuPont CRG, 1999) and an HQ of 12,000 (see Table 6-2 of the SLERA). It was also noted on page 22, Section 6.2.1, Bulk Sediment of the SLERA, “Aniline 1,2-dichlorobenzene, and 1,4-dichlorobenzene were the semi-volatile COPECs with the greatest HQs”.*

DuPont Response: The SLERA will be revised to more clearly present the progression from the preliminary exposure evaluation to the refined exposure evaluation for sediment. Table 6.2 presents a preliminary direct contact evaluation based on the most conservative exposure scenario, which compares the maximum concentration of aniline to a conservative ESV. Table 7.1 presents a refined direct contact evaluation that compares the UCL₉₅ exposure concentrations to refined ecological benchmarks. Table 7.1 will be modified to include each constituent, including aniline, from Table 6.2 with maximum concentrations exceeding ESVs to clarify the progression from the preliminary direct contact evaluation to the refined direct contact evaluation.

If you have any questions, please email me at Edward.J.Lutz@chemours.com or call me at 302-773-4293.

Sincerely,

Edward J. Lutz, P.E.

Notes:

B, Not detected substantially above the level reported in the laboratory or field blanks.

J, Analyte present. Reported value may not be accurate or precise.

R, Unusable result. Analyte may or may not be present in the sample.

U, Not detected.

UJ, Not detected. Reporting limit may not be accurate or precise
